GARLAND, G. M., M. D.	

INDEX TO VOLUME CII.

- Aldrich, S. L.** Hydrophobia, case of abominal tumor with ascites, 517.
Amsterdam. The medical congresses at Amsterdam and Baden-Baden, 212.
 Anatomy. Recent progress in anatomy, Dwight, T., 220
 Anthrax. W. E. Inebriety, 12.
 Army. Contract surgeons, 378.
Arnold, G. J. Cases at the Boston City Hospital, 81 chronic rheumatic arthritis and furious renal calculi, 318.
Baltimore. Malaria febre fever, 421.
Bath. The graphic method as applied to physiological investigation, 10.
Ayer, J. B. Scarlet fever, 497; empyema, antiseptic operation, 539.
Baden-Baden. The medical congresses at Amsterdam and Baden-Baden, 212.
Bannon, H. T. The medical law of North Carolina, 380.
Baker, W. H. Cystocele, 11; recent progress in gynecology, 33.
Baltimore. Letter from Baltimore, 176.
Barlowe, F. Malarial febre fever, 421.
Bartholow, R. Case of typhoid fever, and the so-called specific treatment, 169.
Battery, R. New method of intra-uterine surgery, 477.
Beecher, O. H. Anterior syphilis, 35; lumbago sciatica, 219; a new autopsic, 239; recovery from severe injuries, 230; recent progress in surgery, 555.
Becker, A. I. Puerperal coarulsions, 126.
Bellevue, N. Y. Case of total color-blindness, 441.
Bibliography. Establishment of a Medical Library in Rhode Island, 12; Hofmann, K. B., and Uitzmann, R., Guide to the Examination of the Urine, 13; Harlan, G., American Health Primers, Eye-sight, and How to Care for it, 13; Association of Medical Officers of American Institutions for Foreign Service—Third Annual Proceedings, 13; Holden, J., and Langton, J., Manual of the Dissection of the Human Body, 11; Thompson, H., Clinical Lectures on Diseases of the Urinary Organs, 14; Landolt, E., a Manual of Examination of the Eyes, 15; Clifford, W. L., Nature and Signs of Disease, 15; Transactions of the Medical Society of the State of Massachusetts, 15; Brown, F. H., The Medical Register for New England, 15; Mays, T. J., Consumption and How to Prevent it, 15; Fewell, S., Outlines of the Practice of Medicine, 30; Playfair, W. S., a Treatise on the Science and Art of Surgery, 63; Roberts, F. T., The Theory and Practice of Medicine, 63; Harvey, A., First Lines of Therapeutics as Based on the Modes and the Processes of Healing as Occurring Spontaneously in Disease, and on the Modes and the Processes of Dying as Resulting naturally from Disease, 63; The Second Medical Volume of the Journal of Surgical Pathology, 63; Notes on the History and Progress of F. J., The Pathology and Treatment of Venereal Diseases, 50; Keating, J. M., With General Grant in the East, 87; Transactions of the American Medical Association, vol. xxx, 1875-88; Proceedings of the New Hampshire Medical Society, 87; Transactions of the Medical Association of the State of Missouri, 92; The American Journal of Orthopedy, 110; Early, P., Studies Relating to the Curability of Insanity, 111; Charcot, J. M., Lectures on the Diseases of the Nervous System, 130; Cutter, E., Primer of Clinical Microscopy, 130; Byrnes, J. S., a Treatise on the Theory and Practice of Medicine, 130; Elements of Modern Chemical Physiology, Fox, G. H., Photographic Illustrations of Skin Diseases, Parts V and VI, 159; Elsberg, L., The Structure and other Characteristics of Colored Blood Corpuscles, 159; Annual Report of the Marine Hospital Service, 160; America's Pharmacy, 160; Transactions of the American Medical Association, 160; The Mouth and Teeth, 183; Guy's Hospital Gazette, 181; Klein, E., and Smith, E. N., Atlas of Histology, 206; Beale, L. S., How to Work with the Microscope, 207; Annals of the Anatomical and Surgical Society, 207; Warder, H. G., Drainage and Overwork, 207; Cutler, G. R., A Dictionary of the German Terms used in Medicine, 222; Syllabus of a Course of Lessons on Physiology, 232; Sparks, E. L., The Riviera, Sketches of the Health Resorts on the North-Mediterranean Coast of France and Italy, From Hyeres to Spezia, 232; Fleischer, F. A., and Hanley, A., Phlegmon, or Abscess, 232; The Medical Directory of the United Kingdom in Great Britain and British India, 254; Cornil, V., and Ranvier, L., A Manual of Pathological Histology, 255; The Alienist and Neurologist, 255; Foster, M., A Text-book of Physiology, 255; Jones, W. R., Elements of Human Anatomy, 255; The Principles of Medicine, 255; Notes on Diseases of the Testis, 270; Morris, M., Skin Diseases, including their Definition, Symptoms, Diagnosis, Prognosis, Morbid Anatomy, and Treatment, 270; Roberts, W., Urinary and Renal Diseases, 303; The North American Review, 303; Kouth, C. H., Food Feeding and its Influences on Life, 322; Andrus, J., The Pathology of Man, 322; The American Medical Association, 322; The Crayfish, an Introduction to the Study of Zoology, 351; Lombard, J. S., Experimental Researches on the Regional Temperature of the Head, 352; Ellis, C., Bibliography of Albuminuria, 361; Medical and Surgical History of the United States Army during the War of 1861-1865, 361; The Bulletin of the Board of Health, Lunacy, and Charity, 378; Leonard, C. H., The Hair, its Growth, Care, Diseases, and Treatment, 393; Galabin, A. L., Student's Guide to the Diseases of Women, 393; Reynolds, J. R., A System of Obstetrics, 428; Clark, H. G., The Spectroscope in Medicine, 428; Croome, W. H., Minor Gynaecological Operations, 428; Phillips, J. D., Sturgis, F. R., The Student's Manual of Venereal Diseases, 442; Dennis, J. H., A Few Cases of Leprosy, 448; Keyes, E. L., The Venereal Diseases, including Stricture of the Male Urethra, 449; Whitaker, J., The Student's Manual of Venereal Diseases, 449; West, Charles, Lectures on Genital Central Localization, 456; West, Charles, Lectures on the Diseases of Women, 455; Darling, William, and Rumney, A. L., The Essentials of Anatomy, 455; Roberts, J. B., Paracarcinoma of the Pericardium, 519; Roberts, J. B., Paracarcinoma of the Heart, 519; Roberts, J. B., Paracarcinoma of the Liver, 519; Roberts, J. B., Paracarcinoma of the Lung, 519; Roberts, J. B., Paracarcinoma of the Pancreas, 519; Roberts, J. B., Paracarcinoma of the Spleen, 519; Roberts, J. B., Paracarcinoma of the Stomach, 519; Roberts, J. B., Paracarcinoma of the Testis, 519; Roberts, J. B., Paracarcinoma of the Uterus, 519; Roberts, J. B., Paracarcinoma of the Vagina, 519; Roberts, J. B., Paracarcinoma of the Vulva, 519; Roberts, J. B., Paracarcinoma of the Penis, 519; Roberts, J. B., Paracarcinoma of the Scrotum, 519; Roberts, J. B., Paracarcinoma of the Epididymis, 519; Roberts, J. B., Paracarcinoma of the Vas Deferens, 519; Roberts, J. B., Paracarcinoma of the Seminal Vesicle, 519; Roberts, J. B., Paracarcinoma of the Prostate, 519; Roberts, J. B., Paracarcinoma of the Bladder, 519; Roberts, J. B., Paracarcinoma of the Ureter, 519; Roberts, J. B., Paracarcinoma of the Kidney, 519; Roberts, J. B., Paracarcinoma of the Adrenal Gland, 519; Roberts, J. B., Paracarcinoma of the Thyroid Gland, 519; Roberts, J. B., Paracarcinoma of the Parathyroid Gland, 519; Roberts, J. B., Paracarcinoma of the Pituitary Body, 519; Roberts, J. B., Paracarcinoma of the Hypophysis, 519; Roberts, J. B., Paracarcinoma of the Pineal Body, 519; Roberts, J. B., Paracarcinoma of the Optic Chiasm, 519; Roberts, J. B., Paracarcinoma of the Infundibulum, 519; Roberts, J. B., Paracarcinoma of the Third Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fourth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fifth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Sixth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Seventh Ventricle, 519; Roberts, J. B., Paracarcinoma of the Eighth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Ninth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Tenth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Eleventh Ventricle, 519; Roberts, J. B., Paracarcinoma of the Twelfth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Thirteenth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fourteenth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fifteenth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Sixteenth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Seventeenth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Eighteenth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Nineteenth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Twentieth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Twenty-first Ventricle, 519; Roberts, J. B., Paracarcinoma of the Twenty-second Ventricle, 519; Roberts, J. B., Paracarcinoma of the Twenty-third Ventricle, 519; Roberts, J. B., Paracarcinoma of the Twenty-fourth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Twenty-fifth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Twenty-sixth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Twenty-seventh Ventricle, 519; Roberts, J. B., Paracarcinoma of the Twenty-eighth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Twenty-ninth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Thirtieth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Thirty-first Ventricle, 519; Roberts, J. B., Paracarcinoma of the Thirty-second Ventricle, 519; Roberts, J. B., Paracarcinoma of the Thirty-third Ventricle, 519; Roberts, J. B., Paracarcinoma of the Thirty-fourth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Thirty-fifth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Thirty-sixth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Thirty-seventh Ventricle, 519; Roberts, J. B., Paracarcinoma of the Thirty-eighth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Thirty-ninth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fortieth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Forty-first Ventricle, 519; Roberts, J. B., Paracarcinoma of the Forty-second Ventricle, 519; Roberts, J. B., Paracarcinoma of the Forty-third Ventricle, 519; Roberts, J. B., Paracarcinoma of the Forty-fourth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Forty-fifth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Forty-sixth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Forty-seventh Ventricle, 519; Roberts, J. B., Paracarcinoma of the Forty-eighth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Forty-ninth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fiftieth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fifty-first Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fifty-second Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fifty-third Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fifty-fourth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fifty-fifth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fifty-sixth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fifty-seventh Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fifty-eighth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Fifty-ninth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Sixtieth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Sixty-first Ventricle, 519; Roberts, J. B., Paracarcinoma of the Sixty-second Ventricle, 519; Roberts, J. B., Paracarcinoma of the Sixty-third Ventricle, 519; Roberts, J. B., Paracarcinoma of the Sixty-fourth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Sixty-fifth Ventricle, 519; Roberts, J. B., Paracarcinoma of the Sixty-sixth Ventricle, 519; Roberts, J

- W. Child, 190; elephant breeding, 209; sea-side ethics, 236, 283, 309; the new code, 231; letters from St. Louis, 454, 476; the decennial convention for revision of the Pharmacopæia, 474; letter from Baltimore, 476; letter from New York, 571.
- Cowley, E. A.** Non-pretent in English and Scotch asylums, 574.
- Curtis, H.** Medical cases in the service of Dr. Hall Curtis, 465.
- Curtis, T. B.** Recent progress in urinary surgery, 316; sudden and transient swellings of the lips, 445, 556.
- Cushing, E. W.** The coming era, 32.
- Cushing, E. W.** Law to regulate the practice of medicine, 180.
- Cutaneous System.** Eruption following the use of salicylate of soda, 22; case of multiple melanoma-sarcoma of the skin, Buckley, L. D., 218; recent progress in dermatology and syphilis, Wigglesworth, E. B., 234, 310; case of violent ulcer, ligature of carotid artery, recovery, Irwin, S., 509.
- Cutler, E. G.** Pathological changes in septicæmia and pyæmia, 302; recent progress in pathology and pathological anatomy, 463, 485.
- Da Costa, J. M.** A case of Graves's disease (exophthalmic goitre), with remarks upon its pathology, etiology, and treatment, 337; parotid swelling after typhoid fever, 340.
- Dale, J. T.** A new remedy in the treatment of diabetes, 216.
- Davenport, E. F.** Recent progress in pharmaceutical preparations, 325.
- Davis, H. G.** Treatment of paralysis in early life, 293.
- Davis, W. B.** Intestinal obstruction, 183, 201.
- Derby, H.** On the prevention of near-sight in the young, 553, 558, 620.
- Dickman, H. B.** Medicine in the United States, 20.
- Digestive System.** Difficult dentition, Eucklingham, E. M., 3; parotitis in fevers, Lyman, G. H., 155; intestinal anti-peristalsis, 214; intestinal obstruction, Davis, W. B., 183, 201; forced alimutation, Hutchins, A., 222; herniotomy, P. C. B., 222; bean ingestion, Hutchins, A., 222; gallstones, J. F., 262; the treatment of freckles, Hanna, Warren, J. C., 276; urgent vomiting in pregnancy, Minot, F., 302; difficult dentition, Eucklingham, E. M., 322; parotid swelling after typhoid fever, Da Costa, J. M., 340; sudden and transient swellings of the lips, Curtis, T. B., 445, 556; the radical cure of hernia, Warren, J. H., 452; intestinal obstruction, Eucklingham, E. M., C. B., 540.
- Draper, F. W.** Recent progress in forensic medicine, 161; sacculated bladder, 225.
- Ductless Glands.** A case of Graves's disease (exophthalmic goitre), Da Costa, J. M., 337.
- Dwight, T.** Recent progress in anatomy, 250.
- Ear.** Children's earache, Blake, C. J., 130; impacted foreign bodies in the external auditory meatus, Brown, F. L., 221; necrosis of the inner table of the mastoid and caries of the tympanum, Green, J. O., 324; necrosis of the tympanum with destruction of the ossicles, Green, J. O., 324; caries of the mastoid, Green, J. O., 325; foreign bodies in the ear, Green, J. O., 374; affections of the middle ear during the early stages of syphilis, Sturgis, F. R., 531; report on the progress of otology, Green, J. O., 611.
- Eales, R. T.** The treatment of hæmorrhoids, 485; the treatment of hæmorrhoids, 485; apoplexy, 48, 60; letter from Dr. Polk, 113; abscess of the brain, 417; some of the symptoms of Bright's disease, 104.
- Editorials.** Introductory, 16; the Bellevue Training School for Nurses, 16; codes of ethics, 40; the annual volume of the Medical and Surgical History of the War of the Rebellion, 64; Harvard University and female physicians, 88; the transactions of the American Medical Association, vol. xxx., 1879, 88; the New Hampshire Medical Society, 89; report of the health officer of the State of New York, 113; the diploma degree of the Boston Board of Health, 113; Dr. Bowditch's retirement from the Massachusetts Board of Health, 137; the children's hospital in Boston, 138; ethics and women, 160; annual report of the marine hospital service, 167; a proposed act to regulate the practice of medicine in Massachusetts, 194; examinations for color-blindness and defective sight among railroad employees, 208; John Neill, M. D., 208; the New York State Board of Charities, 209; medical charities and the profession, 233; the new code of ethics of the Massachusetts Medical Society, 250; lunacy reform, 257; stone in the bladder, litholapaxy, 258; the duty on quinine, 259; health of large English towns, 259; model school-houses, 280; the argument of the council for the Social Science Association before the joint legislative committee on public health, 294; medical practice on the stage, 306; the alcohol question from a medical point of view, 328; the administration of charities in New York, 353; further progress in medical education, 377; sale of diplomas by fraudulent corporations, 377; the supplementary report of the Health Department of the Board of Health, Lunacy, and Charity, 377; the annual volume of the Medical and Surgical History of the War of the Rebellion, 40; an unusual mode of suicide, 424; speculation in opium, 425; the Warren price, 426; insane asylums in the United States, 449; first annual report of the Board of Health of the taxing district of Shelby County (city of Memphis), 450; production of evil will, 471; second annual report of the Connecticut Board of Health; seventh annual report of the Board of Health of the City of New Haven, 472; the State Board of Health, Lunacy, and Charity, 497; the physiological laboratory at Harvard, 497; a special investigation in hygiene in the public schools of Boston, 521; suits for fees, 522; the meeting in New York, 544; annual meeting, 568; a convalescent hospital, 580; a singular case of epidemic in Berkshire County, 617; the discussion on the appropriation for the National Board of Health, 617; the discussion on the appropriation for the National Board of Health, 617.
- Ellis, C.** The significance of albuminuria as a symptom, 223, 361, 385, 414.
- Engelmann, G. F.** The posture of women during labor, 568.
- Evans, J. H.** Griffe's supra-condylar amputation of the thigh, 21.
- Eye.** Neurotomy of the optic nerves as a means of relieving the elevation of the eyeball, Williams, H. W., 73, 83; examinations for color-blindness, Magnus, H., 117; examinations for color-blindness and defective vision among railroad employees, 208; neurotomy, Williams, H. W., 225; a piece of metal twenty-three years in the eye without causing a sympathetic ophthalmia, Chisolm, J. J., 248; permanent closure of the palpebral aperture, Streetfield, J. F., 292; glaucoma, Williams, H. W., 278; bony formations in the eyelids, Jeffries, B. J., 278; case of congenital unilateral color-blindness, Jeffries, B. J., 411; parietal affection of ocular muscles, Wadsworth, O. F., 449; color-blindness, Wadsworth, O. F., 526; color-blindness, Jeffries, B. J., 455, 493; hypnotic color-blindness, 526; on the prevention of near-sight in the young, Derby, H., 553, 558; Near-Sight in the Young, Webster, D., 610.
- Field, C. C.** A case of tetanus, recovery after seven weeks, 553.
- Fitch, W. C. B.** Intestinal obstruction, 549.
- Fisher, T. W.** Agoraphobia, 575; the commitment and certification of the insane, 578.
- Fitz, R. H.** Menstruity, 135.
- Folsom, C. F.** Typhoid fever, 227; cures of insanity and of fanaticism, 265; lecture on insanity, 481.
- Forest, W. E.** Remarkable resuscitation, 429.
- Francis, G. E.** The admission of women to the Massachusetts Medical Society, 213.
- Galloupe, L. F.** Death from impacted gall-stones, 262; case of cyclops, 485.
- Garland, G. M.** Prolapsed funis, 227; the principle of the siphon applied to thoracentesis, 376; recent progress in physiology, 458.
- Gay, C. S. F.** Refracture for the correction of deformity from the malunion of bone, 222.
- Gay, C. W.** Cases treated by the Lister method, 8.
- General Diseases.** Scarlatina, Leonard, C. H., 12; diphtheria, a circular of the Boston Board of Health, 113; clinical lecture on the physiology and pathology of syphilis, Wigglesworth, E. B., 234; diphtheria, Lyman, G. H., 155; Dr. Bonstead's new departure on the chancre, Greenough, F. B., 162; a case of typhoid fever, and the so-called specific treatment, Davenport, E. F., 169; a new remedy in the treatment of diabetes, Dale, J. T., 216; case of multiple melanoma-sarcoma of the skin, Buckley, L. D., 218; so-called gallopian syphilis, Sturgis, F. R., 531; the prevention of certain zymotic diseases, Peters, J. C., 225; typhoid fever, Folsom, C. F., 227; a remarkable case of carcinoma, Brockway, G. H., 246; a case of typhoid fever during pregnancy, Hardon, V. O., 247; anular, perianal, and Bartholin's cyst, 251; carcinoma of the mammary gland, Gross, S., 259; epithelioma of the cervix removed by curette and scissors, Boardman, W. E., 301; fibroid tumor of the uterus, Putnam, J. J., 302; pathological changes in septicæmia and pyæmia, Cutler, E. G., 302; pathological changes in septicæmia and pyæmia, Cutler, E. G., 302; diphtheria, with long period of incubation, Wells, F., 340; chronic rheumatic arthritis and fibrous renal calculi, Arnold, G. J., 348; case of malignant disease of the uterus, Morrill, F. G., 353; recent progress in dermatology and syphilis, Wigglesworth, E. B., 354; the treatment of hæmorrhoids, 485; diphtheria, Albert, S. L., 489; rapid death in the early stages of diphtheria, Nichols, A. H., 494; affections of the middle ear during the early stages of syphilis, Sturgis, F. R., 531; the aetiology of fever, Walton, G. L., and Wheeler, C. B., 555.
- Generative System.** Cystocele, Baker, W. H., 11; recent progress in gynecology, Baker, W. H., 11, 33; on strangulated veins of the uterus, Buckner, T. H., 56, 74; ovarian cysts, Romans, J., 58, 227; antiquity of hysterectomy, Romans, J., 58, 227; hysterectomy, Romans, J., 58, 227; mechanical compression in orchitis, White, O. A., 99; clinical lectures on diseases of women, Thomas, T. G., 105; Senozon in rhyme, 214; Thomas Keith and ovariotomy, 222; some observations on the treatment of inter-uterine pregnancies, Boardman, W. E., 240; hysterotomy, Homans, J., 278; on certain intra-uterine displacements, Wing, C. E., 298; cases in the service of Dr. G. H. Lyman, 339; epithelioma of the cervix removed by curette and scissors, Boardman, W. E., 301; fibroid tumor of the uterus, Putnam, J. J., 302; removal of the parovarium and ovaries, Boardman, W. E., 301; the genital organs, Sayre, L. A., 312; cases of ovariotomy, Clarke, H., 344; hot rectal catheters, Chadwick, J. R., 349; case of malignant disease of the uterus, Morrill, F. G., 353; two cases of hysteroneurosis, Lyman, G. H., 353; diagnosis of ovarian cancer, Boardman, W. E., 353; vaginal injections, Richardson, W. L., 443; protection of sex at will, 471; new method of intra-uterine medication, Battey, R., 477; recto-vaginal fistula cured without operation, Brown, L., 501; cerebral hemorrhage and rupture of the uterus, Streetfield, J. F., 292; the proper use of the hot vaginal douche, Wing, C. E., 563.
- Gray, J. P.** Use of hyoseyamine in insanity, 204.
- Green, C. M.** Puerperal tetanus, 343.
- Green, J. O.** The treatment of the disease in the lateral sinus and emissary mastoid vein, 324; necrosis of the inner table of the mastoid, and caries of the tympanum, 324; necrosis of the tympanum, with destruction of both labyrinth, 325; caries of the mastoid, 325; foreign bodies in the ear, 374; Report on the progress of otology, 611.
- Greenough, F. B.** Dr. Bonstead's new departure on the chancre, 162.
- Griffith, M. M.** Crude petroleum in asthma, 453.
- Gross, S. B.** Carcinoma of the mammary gland, 259.
- Ham, O. F.** A case of pyelo-nephritis, 557.
- Hamilton, A. McL.** Use of nitrous oxide gas in certain diseases of the nervous system, 461.
- Hardon, V. O.** The metric system in the marine hospital service, 546.
- Hamilton, S. N.** Absence of amniotic fluid, 229.
- Hardon, V. O.** A case of typhoid fever during pregnancy, 247.
- Harris, F. A.** Case of carbolic-acid poisoning, 494.
- Hart, P. A. R.** The treatment of hæmorrhoids, 485.
- Hayden, D. H.** Recent progress in the treatment of children's diseases, 51, 79.
- Hill, H. E.** Three cases of litholapaxy, 201.
- Hill, W. V.** Recent progress in medical chemistry, 127.
- Hodgdon, R. L.** An obscure local trouble in the region of the sternum in a child, 518.
- Hodges, R. M.** Constriction of the spine, so called, 192.
- Homan, J.** Ovarian cysts, 55, 227, 417; ovariotomy, 55, 275; operating table, 447.
- Hosmer, A.** Teratoma, 61; antiquity of intra-uterine injections, 63.
- Hunt, D.** The proposed medical act, 213.
- Hunter, C. F.** The leather jacket in the treatment of spinal curvature, 582.
- Hutchins, A.** Forced alimutation, 222.
- Hygiene, Health, and Boards of Health.** Sewerage, Noyes, R. H., 12; sanitary organization of the nation, Bowditch, L. I., 26; report of the health officer of the port of New York, 112; diphtheria, a circular of the Boston Board of Health, 113; Dr. Bowditch's retirement from the Massachusetts Board of Health, 137, 138; health of large English towns, 259; model school-houses, 280; the National Board of Health, 485; health legislation at Washington, 400; a bill to increase the efficiency of the National Board of Health, 400; report of the Board of Health of Memphis, Tenn., 460; report of Connecticut Board of Health, 472; report of Board of Health of New Haven, 472; the State Board of Health, Lunacy, and Charity, 497; a special instructor in hygiene in the public schools of Boston, 521.
- Instruments and Apparatus.** Pond's sphymograph, 104; nasal probe, Theobald, T., 333; a new vernicular sound and catheter, Warren,

- J. H., 357; Thomas's orthopedic splints, Post, A., 374; the compound epiphyseograph, Key, A. T., 481; operating table, Homan, J., 447; the leather jacket in the treatment of spinal curvature, Hinton, C. T., 582.
- Irvine, Fairfax.** Case of rolent ulcer, ligature of carotid artery, recovery, 603.
- James, W.** The sensibility of articular surfaces, 94.
- Jeffries, B. J.** Bony formations in the eyeball, 275; color-blindness, 455, 459; hypotic color-blindness, 529.
- Jewett, G.** The Hayden case; poisoning by oil of tansy, 237.
- Jurisdiction.** Medical law, 13; the commitment of the insane, Cushing, H., 32; recent progress in forensic medicine, Draper, F. W., 143; suicide by chloral, suicide by cathartics, Brown, E. F., 107; the Hayden case, Jewett, G., 148; law to regulate the practice of medicine, Cushing, E. W., 180; a proposed act to regulate the practice of medicine in Massachusetts, 184, 191; summary of important points in the Standard cases established by medical evidence, Peckham, C. T., 157; an unusual mode of suicide, 424.
- Kane, H. H.** Hydrate of chloral, 429.
- Keith, T. H.** Thomas Keith and ovariotomy, Sims, J. M., 221.
- Key, A. T.** The prophylactic interval of time required to start the arterial pulse after the beginning of the systole of the ventricle, 407; the compound epiphyseograph, 451.
- Knight, F. L.** Recent progress in the treatment of thoracic diseases, 153, 171; the dangers of fluorocauteris and injections into the pleural cavity, 397.
- Lawrence, R. M.** The inhalation of ethyl iodide for the relief of dyspnea, 428.
- Leaming, J. R.** Endemic pleuro-pneumonia as seen in New York during the past ten or twelve years, 265.
- Leonard, C. H.** Scrofula, 13.
- Life Insurance.** One of the causes of death in a life-insurance company, Severens, J., 341; life insurance run mad, 382.
- Lister.** Antiseptic surgery, 116, 140.
- Local Injuries.** Rupture of a tendon, Bigelow, H. J., 217; cases of Colles's fracture, Bolles, W. F., 198; the mechanism of the dislocation of the clavicle in a child ten months old, Wright, T. R., 323.
- Locomotion, Organs of.** Pott's disease of the spine, Sayre, L. A., 1, 145; sensibility of articular surfaces, James, W., 94; lateral curvature of the spine, Sayre, L. A., 221; torcularis successfully treated by Delorme's method, Bradford, E. H., 522; fibrous ankylosis successfully treated by the brisement force, Sayre, L. A., 385; extra-capsular fracture in a knee formerly the seat of joint disease, but now entirely free from it, Sayre, L. A., 385; chronic inflammation of the knee joint, Sayre, L. A., 395; ankylosis due to extra-capsular disease, Sayre, L. A., 387; treatment of Pott's disease by plaster-of-Paris jacket, Bradford, E. H., 450; spina bifida treated with plaster-of-Paris dressing, Sayre, L. A., 529; the leather jacket in the treatment of spinal curvature, Hinton, C. T., 582.
- Lyman, G. H.** Slight lacerations of the perineum, 60; proctitis in fevers, 135; the treatment of the placenta in abortion, 300; cases in the service of Dr. Lyman, 319; two cases of hysterio-neurosis, 440.
- McClellan, A. S.** Infantile convulsions, 22.
- McGinnis, H.** Examinations for color-blindness, 117.
- Malformations.** Cephaloheutoma, Sabine, G. K., 251; case of cyclops, Gailloche, I. F., 461; malformation of the ear, 528.
- Marine Hospital Service.** Annual report of the Marine Hospital Service, 190; metric system in the Marine Hospital Service, Hamilton, J. B., 546.
- Mason, H. E.** Extensive venous thrombosis, 359.
- Mason, A. L.** Cases at the Boston City Hospital, 81; recent progress in the theory and practice of medicine, 274, 286.
- Materialia Medica et Therapeutica.** Eruption following the use of salicylate of soda, 22; the relation of drug manufacture to the progress of therapeutics, Edes, R. T., 48, 60; antiquity of intra-uterine injections, Hosmer, A., 63; laborant, Child, W., 11; mechanical compression in orchitis, White, O. A., 49; suicide by chloral, suicide by cathartics, Brown, E. F., 107; antiseptic surgery, Lister, H., 140; sixth decennial pharmacopoeia convention, Morgan, J. E., 168; case of typhoid fever, and the so-called scific treatment, Bartholow, R., 169; recent progress of materia medica and pharmacy, Bolles, W. F., 198; use of hypocyania in insanity, Gray, J. P., 204; anesthetic, 211; compound, Spencer, E. B., Jr., 214; a new remedy in the treatment of diabetes, Dale, J. S., 216; the physiology of opium poisoning, Nivison, 224; the duty on quinine, 259; poisoning by oil of tansy, Jewett, G., 257; a new antiseptic, Bench, H. B., 249; the use of ergot, Wellington, W. L., 249; the medicinal form, 419; the alcohol question from a medical point of view, 228; the inhalation of ethyl bromide for the relief of dyspnea, Lawrence, R. M., 428; treatment of the cinchona tree in California, 423; metric system, 546; the theory and practice of medicine, Kane, H. H., 424; metritis, 546; metrorrhagia, Richardson, W. L., 443; speculation in opium, 425; crude petroleum in asthma, 441; health, 453; decennial convention for revision of the Pharmacopoeia, 474; treatment of Pott's disease by the plaster-of-Paris jacket, Bradford, E. H., 452; use of uterine oxide in certain diseases of the nervous system, Hamilton, A. McL., 469; new method of intra-uterine medication, Hattey, R., 472; recent progress in pharmaceutical preparations, Davenport, B. F., 544; bromide of ethyl, Roberts, J. B., 541; the proper use of the hot vaginal douche, Wing, E. E., 583; prophylactic use of col-lier's fluid, Thomson, W. H., 587; Vase's antiseptic, Chassey, T. B., 569.
- Medical Schools and Colleges.** Bellevue Hospital Training School for Nurses, 16; Harvard University and female physicians, 88; the Johns Hopkins University and higher education, with a glance at the hospital buildings, Boyland, G. H., 57; further progress in medical education (Harvard University), 377; prize essays, 478; Johns Hopkins University, 502; the physiological laboratory at Harvard, 457; Massachusetts College of Pharmacy, 594; medical education in the United States, Bidana, H. B., 595.
- Metric System.** Use of the metric system, 162; metric system, 546; metric system in the Marine Hospital Service, Hamilton, J. B., 546.
- Millet, A.** Admission of women to the Massachusetts Medical Society, 528.
- Mind.** The commitment of the insane, Cushing, H., 32; use of hypocyania in insanity, Gray, J. P., 204; lunacy reform, 257; recent progress in insane asylum management, Channing, W., 243; cases of insanity and functional, Folke, C. J., 243; study of Cyclopedia of Psychiatry, Channing, W., 315; non-restraint in English and Scotch asylums, Cowles, E., 374; insane asylums in the United States, 440; lecture on insanity, Folson, C. F., 481; the commitment and certification of the insane, Fisher, T. W., 458; lunacy supervision, 509.
- Minot, F.** Rapid pulse and high temperature as symptoms of purpural inflammation, 117; urgent vomiting in pregnancy, 392; pneumonia, sudden death, 368.
- Morgan, J. E.** Sixth decennial pharmacopoeia convention, 168.
- Morrill, F. G.** A case of malignant disease of the uterus, 153.
- Nervous System.** Four cases of cerebro-spinal meningitis, Clark, F. C., 35; purpural convulsions, Becker, A. R., 126; concussion of the spine, so called, Hodges, R. M., 132; myelitis, Webber, S. G., 157, 173; meningo-encephalitis, Williams, H. W., 225; tetanus, 180; paralysis in the face, Davis, H. G., 233; urgent vomiting in pregnancy, Minot, F., 392; partial paralysis and loss of coordination from irritation of the genital organs, Sayre, L. A., 312; tumor of the cerebellum, Webber, S. G., 318; localized suppurative meningitis and softening with cerebral paralysis, Putnam, J. J., 340; a series of cases characterized by numbness of the hands, Putnam, J. J., 375; agoraphobia, Fisher, T. W., 375; hysterics, 382; two cases of hysterio-neurosis, Lyman, G. H., 440; abscess of the brain, Edes, R. T., 47; use of uterine oxide in certain diseases of the nervous system, Hamilton, A. McL., 469; purpural tetanus, Green, C. M., 493; a case of tetanus, recovery after seven weeks, Field, C. C., 530; pseudo-muscular hyper trophy, Putnam, J. J., 538; cerebral hemorrhage and fibrous tumors of the cranium, Struttack, G. C., 550.
- New Orleans.** Letter from New Orleans, the Auxiliary Sanitary Association, 189.
- New York.** A day in New York, 188; the New York State Board of Charities, 208; the administration of charities in New York, 355; letter from New York, 574.
- Nichols, A. H.** Rapid death in the early stages of diphtheria, 491.
- Nivison.** The physiology of opium poisoning, 224.
- Nosse.** Nasal prolepsis, Theobald, T., 353.
- Nurse.** 12.
- Nursing.** Registry for nurses, Putnam, C. P., 12; Bellevue Hospital Training School for Nurses, 16.
- Oliver, J. P.** The treatment of asthma, 238.
- Orthopedic Surgery.** Clinical lectures, Pott's disease of the spine, Sayre, L. A., 1, 145; club foot and hand, Bradford, E. H., 221; recent progress in orthopedic surgery, Bradford, E. H., 370.
- Otis, E. N.** Clinical lectures on the physiological pathology of syphilis, 121.
- Park, R., and Hatfield, M. P.** The abuse of medical charities, 556.
- Parson, J. W.** Death from narcosis, 524.
- Pathology.** Tetanus, Hosmer, A., 61; physiological pathology of syphilis, Otis, E. N., 121; monstrosity, Fitz, R. H., 135; pathological changes in septicaemia and pyemia, Cutler, E. G., 302; recent progress in pathology and pathological anatomy, Cutler, E. G., 305, 485; case of cyclops, Gailloche, I. F., 461.
- Peckham, C. T.** Summary of important points in the Standard case as established by medical evidence, 157.
- Pepper, William.** The treatment of asthma, 241.
- Peters, J. C.** The prevention of certain zymotic diseases, 225.
- Philadelphia.** Letters from Philadelphia, 69, 285.
- Physiology.** Sensibility of articular surfaces, James, W., 94; graphic evidence in the physiology of the admission of women to the Massachusetts Medical Society, Otis, E. N., 121; the case of sleep, Smith, W. E., 435; recent progress in physiology, Garland, G. M., 438.
- Poisons.** Ichthyol, Anthony, W. E., 12; eruption following the use of salicylate of soda, 22; the Hayden case, Jewett, G., 148; country practice, lead poisoning, Child, W., 190; summary of important points in the Standard case as established by medical evidence, Peckham, C. T., 157; the physiology of opium poisoning, Nivison, 224; poisoning by oil of tansy, Jewett, G., 257; a case of typhoid fever, and the so-called scific treatment, Bartholow, R., 169; effects of the advocacy of the Standard case, Parsons, T. W., 334; case of carboic acid poisoning, Harris, F. A., 434.
- Polk, C. J.** Letter from Dr. Polk, Edes, R. T., 143.
- Porter, C. B.** Exostrophy of the bladder, 153; hereditarity, 227.
- Portland.** Letter from Portland, 20.
- Post, A.** Thomas's orthopedic splints, 374.
- Practice of Medicine.** Medical law, 13; country practice, 22; code of ethics, 205; medical ethics, Sargent, J., 48; Harvard University and female physicians, 88; the code of ethics, 213; the admission of women to the Massachusetts Medical Society, Francis, G. E., 238; the admission of women to the Massachusetts Medical Society, Brown, E. F., 213; the State (Illinois) Board of Health and the colleges, 235; medical practice and the profession, 233; seaside cities, 265, 283, 300; the new code of ethics of the Massachusetts Medical Society, 256; the proposed law to regulate the practice of medicine in Massachusetts, 234 E. S., 325; 44th from narcosis, law, 284; East Boston ethics (new code), 255; medical ethics, Whitney, J. O., 285; recent progress in the theory and practice of medicine, Mason, A. L., 274, 286; the new code, 331; the degree of doctor in medicine and surgery, 331; the council of the Council for the Social Science Association before the joint legislative committee on public health, 304; medical practice on the stage, 305; admission of women to the Massachusetts Medical Society, Millet, A., 528; the medical law of North Carolina, Richardson, W. L., 443; the use of hypocyania, 204; the admission of women to the Massachusetts Medical Society, 501; in regard to fees, Clark, H. G., 550.
- Pregnancy, Affections connected with.** Slight lacerations of the perineum, Lyman, G. H., 440; recent progress in obstetrics, Richardson, W. L., 7; cystocele, Baker, W. H., 11; absence of amniotic fluid, Hunt, N. S., 22; instrumental labor with rupture of the perineum and laceration of the cervix, acute cystitis, Wellington, W. W., 61; purpural convulsions, Becker, A. R., 126; rapid pulse and high temperature as symptoms of purpural inflammation, Minot, F., 177; protracted labor, Garland, G. M., 227; uterine purpural fever, Barker, F., 254; placenta delinquent, Richardson, W. L., 277; the treatment of the placenta in abortion, Lyman, G. H., 249; the use of ergot, Wellington, W. W., 249; urgent vomiting in pregnancy, Minot, F., 392; case of abortion, with instrumental delivery and death on the fourth day following, Bush, J. F., 345; the placental site, Sawyer, F. W., 395; elastic ligature for the cord, White, C. H., 402; the Boston Lying-in Hospital, 403; a delivery in Cabot, 401; 457; a new method of performing decapitation, Richardson, W. L., 578.

- puerperal convulsions with albuminuria, Sinclair, A. D., 444; puerperal tetanus, Green, C. M., 493; case of labor with constriction of the internal os, Stone, L. R., 517; the forceps in relation to rupture of the perineum, Steadman, C. E., 517; a remarkable case of gastrocnemius, Boyland, G. H., 593; the posture of women during labor, Engelmann, G. J., 498; diagnosis of the position of the fetus, Whitney, J. O., 619.
- Putnam, C. P.** Registry for nurses, 12.
- Putnam, J. J.** Fibroid tumor of the uterus, 502; localized suppurative meningitis and softening with all localized paralysis, 449; foreign body in the urethra, 875; a series of cases characterized by numbness of the hands, 555; pseudo-muscular hypertrophy, 528.
- Putnam, S.** Fatal use of the aspirator, 464.
- Respiratory System.** Recent progress in the treatment of thoracic disease, Knight, F. L., 192, 171; endemic pleuro-pneumonia as seen in New York during the past ten or twelve years, Leaning, J. R., 245; the evil consequences of a neglected cold in the head, Roosa, D. B. St. J., 225; the treatment of asthma, Oliver, J. P., 258; fibroid phthisis, Shattuck, F. C., 246; the death of Washington, 381; cases of empyema, Cabot, A. T., 247; the principle of the siphon applied to thoracentesis, Garland, G. M., 276; empyema, Cabot, A. T., 276; the dangers of thoracentesis and injections into the pleural cavity, Knight, F. L., 257; pneumonia, sudden death, Minet, P., 285; the inhalation of ethyl iodide for the relief of dyspnea, Lawrence, K. M., 428; remarkable resuscitation of asphyxiated new-born child, Forest, W. E., 429; crude petroleum in asthma, Griffith, M. M., 455; obscure local trouble in the region of the sternum in a child, Hodgden, R. L., 518; empyema, antiseptic operation, Ayer, J. B., 539; the treatment of asthma, Pepper, W., 541; case of acute catarrhal pneumonia, followed by hydro-pneumothorax and extreme dislocation and rotation of the heart, Steadman, C. E., 606.
- Richardson, M. H.** Chronic interstitial nephritis, 575.
- Richardson, W. L.** Recent progress in obstetrics, 7; placenta dimidiata, 277; uterine and vaginal injections, 443; cases at the Boston Lymington Hospital, 487; a new method of performing decapitation, 518.
- Rouch, T.** Malformation of left auricle, 558.
- Roberts, J. B.** Bromide of ethyl, 541.
- Roosa, D. B. St. J.** The evil consequences of a neglected cold in the head, 225.
- Sabine, G. K.** Cephalhematoma, 251.
- St. Louis.** Letters from St. Louis, 454, 476.
- Sanger, E. F.** A case of litholapaxy, 200.
- Sargent, J.** Medical ethics, 45.
- Sawyer, E. W.** The placental site, 465.
- Sayre, L. A.** Clinical lectures on orthopaedic surgery, Pott's disease of the spine, 1, 145; lateral curvature of the spine, 221; partial paralysis and want of coordination from irritation of the genital organs, 312; chronic disease and anchylosis of the knee-joint, 385; fibrous anchylosis successfully treated by brisement force, 385; extra-capsular abscess in a knee formerly the seat of joint disease, but now entirely free from it, 385; chronic inflammation of the knee-joint, 386; anchylosis due to extra-capsular disease, 387; spina bifida treated with plaster of Paris dressing, 529; psoriasis associated in connection with Pott's disease, 529, 530; chronic disease of the wrist joint, 576; address before American Medical Association, 544.
- Seaverns, Joel.** One thousand deaths in a life insurance company, 319.
- Shattuck, F. C.** Fibroid phthisis, 240.
- Shattuck, G. C.** Cerebral hemorrhage and fibrous tumors of uterus, 539.
- Sims, J. M.** Thomas Keith and ovariectomy, 221.
- Sinclair, A. D.** Puerperal convulsions, with albuminuria, 444.
- Smith, W. E.** The cause of sleep, 455.
- Societies.** Academy of Natural Sciences, biological and microscopical section, 18; American Laryngological Association, 507; American Medical Association, 88, 227, 524, 544, 549, 590, 574, 576, 584; American Medical Editors' Association, 552; Anatomical and Surgical Society (Brooklyn, N. Y.), annual, 207; Boston Medical-Psychological Society, 396; Boston Society for Medical Improvement, 38, 89, 422, 177, 229, 276, 328, 397, 445, 489, 558, 613; Boston Society for Medical Observation, 157, 178, 249, 321, 346, 374; Cincinnati Medical Society, 201; Connecticut Medical Society, 595; Connecticut River Valley Medical Association, 542; Iowa State Medical Society, 41, 59; Massachusetts Dental Society, 22; Massachusetts Medical Society, 155, 160, 256, 258, 501, 522, 570; Massachusetts Medical-Legal Society, 616; Medical Congresses at Amsterdam and Baden-Baden, 212; Missouri, Medical Association of the State of, 92; New Hampshire Medical Society, 89; New York Academy of Medicine, 109, 587; New York, City of, Society of the County of, 251, 469; New York, Medical Society of the State of, 428, 221; Obstetrical Society of Boston, 40, 263, 448, 517; Pennsylvania State Medical Society, 540; Rhode Island Medical Society, 12; St. Louis Medical Society, 19; St. Louis Obstetrical and Gynecological Society, 19; Suffolk District Medical Society, 11, 150, 180, 278, 467, 492; White Mountains Medical Society, 276.
- Spicer, E. D., Jr.** Anæsthesia by ethyl bromide, 214.
- Stedman, C. E.** The forceps in relation to ruptures of the perineum, 517; a case of acute catarrhal pneumonia, followed by hydro-pneumothorax and extreme dislocation and rotation of the heart, 465.
- Stone, L. R.** Case of labor, with constriction of the internal os, 517.
- Streetfield, J. F.** Permanent closure of the palpebral aperture, 292.
- Surgis, F. R.** So-called galloping syphilis, 224; affections of the middle ear during the early stages of syphilis, 531.
- Surgery.** Cases treated by the Lister method, Gay, G. W. S.; Griggs's supra-condylar amputation of the thigh, Evans, J. B., 21; litholapaxy, Bigelow, H. J., 30, 38; antiseptic surgery, Beach, H. H. A., 25; surgical operations without ligatures, Warren, J. H., 44; litholapaxy, Caswell, E. T., 101; antiseptic surgery, Lister, 116, 190; refracture for the correction of deformity in the mal-union of bone, Gay, G. W. S., 226; Mr. Bryant and antiseptic surgery, Bryant, T., 228; recovery from severe injuries, Beach, H. H. A., 256; fatal use of the aspirator, Putnam, S., 464; Listerism in India, 430; operating table, Homan, J., 447; the radical cure of hernia, Warren, J. H., 432; fractures at the Rhode Island Hospital, Arnold, G. J., 248; foreign body in the urethra, Putnam, J. J., 875; chronic interstitial nephritis, Richardson, M. H., 575; puerperal convulsions with albuminuria, Sinclair, A. D., 444; a case of pyelo-nephritis, Ham, O. F., 597; some of the symptoms of Bright's disease, Edes, R. T., 601.
- Tubercular.** Nasal probe, 523.
- Thomas, T. C.** Clinical lectures on diseases of women, 105.
- Thomson, W. H.** The prophylactic use of cold-liver oil, 587.
- Tumors.** Tumors upon the sternum, Bigelow, H. J., 217; fibroid tumor of the uterus, Putnam, J. J., 502; case of abdominal tumor with ascites, Adams, B. T., 517; cerebral hæmorrhage and fibrous tumors of the uterus, Shattuck, G. C., 539.
- Urinary System.** Litholapaxy, Bigelow, H. J., 30, 38, 217; litholapaxy, Caswell, E. T., 101; extrophy of the bladder, Porter, C. B., 125; a case of litholapaxy, Sanger, E. Lectures.

CLINICAL LECTURES ON ORTHOPÆDIC SURGERY.

Delivered at Bellevue Hospital, New York.

BY LEWIS A. SAYRE, M. D.,

Professor of Orthopædic Surgery and Clinical Surgery in Bellevue Hospital Medical College.

[Reported for the Journal.]

I. POTT'S DISEASE OF THE SPINE.

GENTLEMEN. — As I have several very interesting cases of Pott's disease to show you to-day, I shall devote the hour almost exclusively to a consideration of that subject.

CASE I. The first is one of a child which was kindly sent me two or three days ago by my friend, Prof. Alfred C. Post, of the university, whom it gives me great pleasure to have present with us on this occasion, and who will now give you a brief history of the case.

(Professor Post spoke as follows: The little patient now before you, gentlemen, was brought to my clinic several months ago with disease of the bodies of the dorsal vertebrae, which it had had for about two years previously. For several months before I saw it the child had also suffered from a large abscess in the lumbar region. This I determined to open in the manner proposed by the late Mr. Callender, of St. Bartholomew's Hospital, whose death has been so much regretted on both sides of the Atlantic, and it was followed by complete success.

In the first place, I evacuated the contents of the abscess by means of a small opening, and then with a syringe, passed in through this, distended the cavity with a solution of carbolic acid of the strength of one to thirty. The latter was now drawn off and reinserted three or four times, until the fluid came from the cavity entirely free from pus. Finally, a compress and bandage were applied for the purpose of keeping up moderate pressure, a drainage tube having first been inserted into the opening; and notwithstanding the fact that this slipped into the cavity by accident, and remained there two or three days, there was never the slightest febrile reaction, or any other unfavorable symptom whatever, succeeding the operation. From this date the patient's general health steadily improved, and in a comparatively short time the part had perfectly healed. This method is certainly a very great advance, for in former times we expected hectic fever as a matter of course after the evacuation of such an abscess, in consequence of the blood-poisoning which was so apt to result. Of course the Pott's disease here still remained the same, and it is in consequence of this that I have sent the child to Professor Sayre.)

Dr. Sayre resumed: It is well known that before this admirable method of Callender, which he terms "hyperdistention of the sac," had been devised, death from septicæmia very frequently followed the opening of these chronic abscesses. Here you see the most splendid result that could possibly have occurred in such a case, and I am happy to show it to you to-day as an example of what has been accomplished by the wisdom and skill which so markedly characterized the great and lamented surgeon who was so recently in our midst. For the treatment of the Pott's disease

extension and the application of the plaster-of-Paris jacket are now required; but as this would not be a satisfactory case for class demonstration, on account of the cries and struggles in which the little one would be almost certain to indulge if it were done here, we will postpone the application of the dressing until after the lecture, when it can be done in the ward.

CASE II. The next case is one of the most marvelous that I have ever seen, on account of the terrible character of the disease, and the perfect cure, with almost no deformity whatever, that has been effected. This little girl was sent to me some time ago by one of the physicians connected with the Hospital for Ruptured and Crippled, on Lexington Avenue, on account of a large tumor that had become developed in the lumbar region. When I first saw her she was wearing one of the "braces" employed in that institution in the treatment of spinal disease, and the iron bar of the instrument divided this tumor in the centre. On removing the apparatus and making a careful examination of the parts, I found that the tumor was an enormous abscess, and there was also a large fluctuating tumor in the groin. Knowing full well the dangers attending the ordinary way of evacuating such abscesses (Mr. Callender's method by hyperdistention of the sac not having then been made known to the profession), I determined to lay it completely open in order to give the freest possible escape to the pus, and so made an incision, of some six or seven inches in extent, the line of which you can still very readily see across the back. I then completely filled the cavity with Peruvian balsam, which acts as an antiseptic by reason of the creosote which it contains, and packed it with oakum, and placed the child in the "wire cuirass." The most marked improvement followed the operation, which gave rise to no unfavorable consequences, and as soon as practicable the plaster jacket was applied, which enabled the child to take exercise in the open air. To-day, I am happy to say, the Pott's disease is entirely cured, and I think I have never in all my experience seen such a good result in so severe a case. I have thought it well to bring it before you, therefore, as an instructive illustration of what nature will accomplish when a fair opportunity is afforded her.

CASE III. Now, to show you what nature does when no assistance is given her in the way of appropriate means for avoiding or overcoming deformity, I introduce this young girl, sixteen years of age, who has long been the subject of Pott's disease, and in whom I think we shall find that complete consolidation has already taken place. You see at a glance how short is her stature, and what marked deformity there is in both the anterior and posterior portions of the chest, there being both the "chicken breast" and the protuberance of the vertebra at the seat of the spinal disease so commonly met with in these cases. In order to determine positively whether there is a chance of securing any improvement, however slight, here (which would be the case if complete consolidation had not yet taken place), we will first mark the curve described by the protuberance at the back as she stands upon the floor, and then, suspending her by the axillæ and head, note whether any difference occurs in this. On applying this test we find, unfortunately, that no change whatever is produced in the curvature at the seat of disease (although a little difference is observed in the compensating curves, as they are called), and hence we conclude that it would be altogether useless to attempt

any course of treatment or apply any apparatus for diminishing the deformity in this patient.

CASE IV. The next case to which I would call your attention is one which is still under treatment, although it is now practically well. This little girl, aged six years, I first saw about eight months and a half ago. When fifteen months old she received a fall, and she complained more or less for two years after this, when a projection upon the spinal column was first noticed. At the time that she was brought to me she was unable to stand or to walk, or even to sit up alone. After extension and the application of a plaster jacket, with a head-rest (the seat of disease being in the upper portion of the spine), she at once began to improve, and in a short time showed a tendency to creep. By two months more she was able to creep all about, and a new jacket and head-rest were now applied. In the mean while the respiratory and other functions greatly improved. The apparatus then applied was worn until just two months ago to-day, when it was again removed. For some time the child has been walking by holding on to some object, but it is now beginning to walk without assistance. This is certainly very gratifying, when we remember that seven months ago it could not even stand. Yesterday a new jacket and head-rest were put on.

This case is a very good example of the advantages of the method of rest in the treatment of this affection. Dr. Post, I know, will agree with me in saying that it was formerly an exceedingly rare thing to get a cure in Pott's disease within a year, yet this child is now to all intents and purposes well, though it has been deemed more prudent to continue the use of the dressing for a short time longer. This is by no means an isolated instance, for I have seen quite a number of cases perfectly cured, without any deformity whatever, inside of twelve months. In old times, on the other hand, the treatment always occupied several years, and, despite our best endeavors to prevent it, there was always deformity resulting.

Pott's disease is simply an inflammatory affection of the vertebral bodies and inter-vertebral disks, and it may occur in any individual whatever, whether in a strumous condition or in robust health; of course, it would be more readily developed in the strumous than in the healthy; but even in the strumous I believe that it is of traumatic origin, and may arise from a blow, a concussion, a wrench, or other injury, which in some instances is so slight as to be entirely overlooked. Whatever may be its origin, however, the disease is nothing but an inflammatory process, which goes on until we have softening and caries or necrosis of the bone and disintegration of cartilage resulting. There is, consequently, retention of pus and a vitiated state of the whole system.

Among the characteristic symptoms of the affection is a peculiar grunting respiration, and all the movements of the patient are very significant. The latter are also eminently suggestive of the plan of treatment which we ought to adopt, since every one of them is made with the idea of keeping the affected parts as perfectly at rest as possible. This the patient accomplishes by means of muscular rigidity, and it is in imitation of nature that we must proceed in our treatment. There is one thing in addition, however, which has been found to be of very great service in facilitating a cure, and that is the removal of the weight of the head and upper part of the trunk, which in a

marked degree tends to increase the disintegration. This indication was formerly carried out by keeping the patient confined to bed; while at the same time scotous, issues, and various forms of counter-irritation were employed locally, which, unfortunately, only had the effect of still further reducing the strength and vitality of the patient.

The great advantage of the modern method of the treatment of Pott's disease is that, while the affected parts are kept perfectly at rest by means of an appropriate dressing, the patient is able to take all the exercise in the open air that is necessary, and thus, by steadily building up his general system, greatly hasten his recovery.

The signs of the presence of the disease vary to a certain extent in accordance with its location. Thus, if it is situated high up in the spinal column, there will be more or less cough, sneezing, and difficulty of swallowing, while, if it is a little lower down, there will be cough and pain in the chest, so that in the early stages the trouble is apt to be mistaken for simply bronchitis; if it is further down, symptoms of indigestion will exhibit themselves, which in a large number of instances are attributed to the presence of worms; and if it is still lower down there will be disturbances of the urinary function and pain in the bowels. In fact, the trouble experienced by the patient is primarily at the peripheral extremity of the nerves passing out from the spinal cord at the point affected, and not at the seat of disease itself; and so, whenever our attention is called to any of the above symptoms, and the cause thereof is not perfectly apparent, we should at once make a careful examination of the spine. If there is Pott's disease, the child will show it in his carriage and in the manner of picking objects from the floor, the spinal column all the time being kept in as rigid a condition as possible. If you ask him to jump, you will find that he comes down in a very gingerly manner upon the toes, and not squarely on his heels. I should put you on your guard, however, in reference to one exceptional form, or rather location, of the disease. What I have just said is true of the affection, provided it is situated in the anterior portion of the bodies of the vertebrae; but if it is confined to the sides of the vertebrae, as occasionally happens, the ordinary symptoms are not produced, and we can cause concussion of the spinal column to be made without causing the patient any inconvenience. We should not rest satisfied in any case, therefore, until we have carefully examined both sides of the spinal column.

CASE V. In the person of this young man I will now exhibit to you each detail of my method of treating Pott's disease by means of the plaster-of-Paris dressing. In the first place, we carefully mark out, by a narrow strip of lead fitted accurately to the part, the amount of curvature while the patient is standing upon the floor, so as to compare it with that which is noticed after suspension. Then, having put on him an elastic shirt, which fits like the skin itself, we suspend him by the head and axilla by means of the apparatus with which you are all now so familiar, and note the difference in the line of the curvature which is thus produced. Before commencing the application of the plaster dressing, a pad should be placed on either side of the projecting spinous processes. The plaster bandages should be made of some material having coarse meshes, such as crinoline, cross-barred muslin, or cheese-cloth, into which recently burned and perfectly dry plaster of

Paris should be thoroughly rubbed. If the weather is damp, it is better to put them in an oven for an hour or two before using, so as to evaporate all the moisture from them.

In making the suspension, the consideration of greatest importance is, *never to carry it beyond the point where the patient is perfectly comfortable.* When the point of greatest comfort to the patient has been reached, we must secure him permanently in the position that he then occupies by means of the plaster bandages carefully rolled around the trunk. As the bandages are being applied, an assistant presses each fold as closely as possible against the body, so as to accurately adapt it to the conformation of the surface, expel all air, and make the dressing perfectly smooth and even. If the patient has recently eaten a hearty meal, it will not be necessary to employ a pad over the stomach and abdomen; but if this is not the case, one should be placed in this position until the plaster has set, so as to allow space for a more distended condition of the parts. In the case of women, and especially of young girls approaching the age of puberty, pads should also be placed over the mammae during the application of the plaster, so as to avoid all pressure upon them by the completed jacket.

In order to facilitate the drying process, I used formerly to employ a hot iron rolled over the surface; but more recently, at the suggestion of Professor Post, I have made use of simply a fan for this purpose, and with equal advantage. The great principle in this method of treatment, let me repeat, is simply to suspend the patient until he is entirely comfortable, and then keep him in this position by means of the plaster jacket, applied as I have described. If you will attend to these two points with the greatest possible care, you can always command success.

When I was in Cork, on the 16th of October last, I saw, in consultation with Mr. McNaughton Jones and Dr. R. De La Cour Corbett, an officer of the British army who had been suffering for two years from Pott's disease, and who had just come home from Bengal in order to sell his commission, as he felt that he was utterly unfit for any further service. Just as he was about to be dismissed from the service, it was suggested to him by Dr. Corbett to try Sayre's plan of treatment by suspension and the plaster-of-Paris jacket. Dr. McNaughton Jones, of Cork, was called in consultation, and assisted Dr. Corbett in applying the jacket on the 4th of May, 1879. At that time he was unable to stand without support, and suffered constant and severe pain even when in the horizontal position, and had a sharp, angular posterior projection in the lower dorsal region. In two days after the application of the jacket he could walk, and in less than one month he was actually able to do full duty as an officer of cavalry, to which branch of the service he belonged.

In this case, the patient was literally rescued from ruin by the plaster jacket; for if it had not been for that, he would have been obliged to sell his commission, and, being a younger son, he had nothing else to depend upon for support. I found that he had continued to do perfectly well from the first, and that there was now every prospect of a speedy and complete cure in his case. He was anxious for me to put a new jacket upon him, but as the one applied by Drs. Corbett and Jones still fitted him in the most admirable manner, there was not the slightest necessity for making any change. Of

course, in the case of growing children it is advisable to renew the dressing more frequently.

But now to return to the case in hand. The patient tells us that he feels perfectly comfortable, the application of the bandages having been completed; and you observe that before the plaster gets firmly set I go in front of him, and with the palms of my two hands press the casing more closely in to the body at the iliac fossae, in order that there may be no pressure upon the bony prominences. This, you will remember, I have already guarded against in part by the adjustment of the pads, to which I previously called your attention. It is on attention to such little details that the success of this treatment in a great measure depends; and if you will only bear them in mind I am confident that you will be able to secure better results by means of it than by any other that has yet been devised.

My usual practice is to place the patient on an air-bed as soon as the dressing is completed, and to keep him there until the plaster has hardened perfectly; but as there is no such bed at hand here, and this patient has stated that he did not feel fatigued, I have allowed him to remain suspended until this hardening has taken place. Before taking him down, we turn the knit shirt over the jacket, at the top and bottom of the plaster casing, and apply a single turn of the plaster bandage over it, so as to make a cleaner and neater finish, and then our jacket is complete. The patient is now able to walk about in a perfectly natural and easy manner, and also to raise himself upon his toes and come down on his heels with a jar, — a thing that was altogether impossible for him to do before the apparatus was applied. Now, however, it gives him no pain whatever.

DIFFICULT DENTITION.¹

BY EDWARD M. BUCKINGHAM, M. D.

THE subject of the following paper was presented to me by my having the care of a case which, while in its main features not unusual, presented certain points of interest, one of which, I think, has not been much discussed, and another, though a matter on which every one has an opinion, depends for its understanding upon certain physiological facts, which I have not seen grouped together.

A boy of one year, having two teeth, and never having fully recovered his strength since being sick with cholera infantum, six months before, had been ill for some days. His diet was a thick mixture of Ridge's food and water, with an equal amount of milk. He had diarrhoea, meal and cheese being mixed with the feces, vomiting, and cough, for which examination of the chest gave no explanation. Milk and water, equal parts, were ordered, with the addition of an alkali. Ridge's food was omitted.

Second day. No vomiting after the second meal, and diarrhoea ceased. Tympanitic abdomen and much rigidity of legs. Fingers in mouth and swollen gum over the middle superior incisors. I cut the gum.

Third to eighth day. Skin of extremities red, shining, swollen, and tender, but without fever. These appearances ended in a sharp line toward the trunk, advanced over the whole surface, faded without desquama-

¹ Read before the Boston Society for Medical Observation, December 1, 1879.

tion, and completed their course in three days. Once only, a little cheese in the dejections. Appetite improved, and in eight days he was well, but the teeth had not appeared.

Thirteen days later I learned that directions had been followed for two days only, during which time he was well; then the proportion of milk had been increased, and cheese had appeared in the faeces. In consequence the alkali had been abandoned and Ridge's food substituted. Matters not improving, milk had been repeatedly reduced, so that for two days the diet had been merely Ridge's food and water. During these days the dejections had been mostly meal, the child had been crying, and the fingers had become rigid. The same diet was ordered as before. He stopped crying on getting it, and had a comfortable night.

The next morning the gums were rather swollen, nowhere much so, and he was cross and restless. At midnight he began breathing with a grunt, and early in the following morning the head was hot, fontanelle throbbing violently, pupils contracted and not reacting, lips livid, jaws set tight, and abdomen tympanitic; the gums were swollen, especially at the site of the old cut. He having been in a warm bath without effect, I again cut in the same place, but owing to the contraction of the jaw, or my own clumsiness, without hitting the tooth. There was more bleeding than usual. During the next fifteen minutes the child got his first sleep in twenty-four hours, and the fontanelle ceased throbbing. On waking at the end of that time, he received an injection, evacuating wind and a little faeces of good appearance. About noon, Dr. C. P. Putnam saw him with me, and made some incisions crossing mine. The pupils were then reacting much better than in the morning, but there were fever and rales in the chest. 6.30 p. m. Had taken food, and had a green dejection. Temperature higher; gums more generally swollen and red, and had bled repeatedly. I cut over four teeth of the lower jaw, and he was bathed and oiled. Three hours later, the temperature still rising, I cut two more teeth, thus completing the incisions wherever the swelling was marked, and he was again bathed. Rigidity continued, and an hour after midnight he died.

An autopsy was made fifty-seven hours after death, Dr. Draper being present. The fontanelle was much sunken. The brain was very much injected; not much serum in the ventricles. No pathological changes. Kidneys and liver normal. Lungs engorged in lower lobes, but crepitant. Calvarium cartilaginous. Heart, bladder, and intestines not examined.

Although the case is, excepting for the continued bleeding, by no means uncommon, it illustrates certain points in the treatment of children, notably gum cutting, the use of starch, and the difference in physiological age. Twice during my attendance the gums were cut. On the first occasion there seems to have been no effect, the improvement being remote, and after much trouble. On the second, the effect, though only temporary, seemed for the moment to be brilliant, the more or less comatose condition of several hours disappearing at once in sleep, the violent throbbing of the fontanelle diminishing from the first, and the pupils, which were greatly contracted and altogether irresponsible to light, being, when next examined, much better in both respects. It remains to be proved that the relief was consequent upon the incisions, but the con-

nection was certainly interesting. That this one cut was not the only thing wanting is shown by the death, which may or may not have been owing, in part, to the delay in completing the incisions. It should be stated, however, that the swelling of the seat of the later incisions was but slight until late in the day.

I have cut into swollen gums on twenty-one different occasions. Of course, this number is altogether too small to be regarded as affording anything more than a slight contribution to the study of the subject, and yet the study of these cases may not be without interest. Of them, one may, I think, be fairly subtracted, because the indications for it were not very marked, and the failure of what had been done as giving a bare chance of relief ought not to be compared with cases in which there was positive expectation of it.

Of the remaining twenty occasions, in one, the first incision in the reported case, the cut entirely failed. In one, the group of cuts on the last day of this patient's life, the incisions, at first promising well, finally utterly failed. The remaining eighteen were all followed rather closely by a certain amount of improvement.

In a few of these cases I have delayed cutting, hoping to reach the desired end by regulating diet, and this may somewhat alter the value of the statistics. It is, however, my impression that in those cases in which I have not been allowed to use the gum lancet improvement has been less rapid. In another group of these eighteen cases, gum cutting has constituted the whole treatment, and in three at least of these last, the fretful child of the previous twenty-four hours has recovered its temper and spirits within an hour, and has had an improved appetite for its next meal, or the next but one.

Two cases seem worthy of especial mention. One, a little girl, still walking and speaking with difficulty, apparently remembering the relief given on a similar occasion with another tooth, asked me to cut her gum. That this was a request, and not an exclamation, was made clear by her coming toward me as she spoke. The other, whose gum I had cut at fourteen months, during the absence of his physician, who had afterward repeated the cut, came to his father, when suffering from a later tooth, with a knife from the dinner table, and a request for the operation. These two cases I allude to because in them the relief to suffering must have been considerable and immediate.

The case we have been considering has for its one unusual, not unique, feature bleeding from the gum, and the cause of this bleeding seems worth investigating. There was an unusually great, but by no means very great, loss of blood at once, and during the afternoon the cut repeatedly oozed, though in the opinion of the nurse to no great extent. This had the effect, when I decided in the early evening to extend the cuts, to make me do it half at a time, in order that I might not have too great a bleeding surface to do with in case of accident, there being still two molar teeth over which I then thought the gum needed cutting, which was done a few hours later. Now the one positive thing shown by the autopsy was that the brain was overcharged with blood, and it has since suggested itself to me that anything that would have helped to restore the natural condition of things there, and anything that would have diminished the uneasiness in the gum, and so lessened the grinding, would have lessened

the probability of bleeding; that is, that there would have been less chance of bleeding had the incisions been finished at once. I offer this as a possible explanation of this case of bleeding, not of all cases, and to ask for criticism.

Then the question of the diet of this child is an interesting one. I hope we shall learn from some one present if teething never causes disturbance in nervous children who are properly fed and cared for. But it is certain that ill-fed children have the reputation of suffering most. Still we hear of so many children who eat all sorts of things and are well, that the question of starch digestion is interesting, and especially so in view of the fact that many children get it in small quantities as an adjunct to milk, and are reported as thriving. In consequence, I have searched for reports of experiments bearing on the subject.

Although the saliva, even of very young children, has been reported to have the power of turning starch into sugar, yet the food must be in contact with it but a very short time before passing into the stomach, and in the stomach of adults at least its diastatic action seems to be hindered.¹

Prospero Sossino,² of Florence, found that the fresh infusion of the pancreas of five young sucklings, dogs, rabbits, and a cat, had no diastatic action upon starch even after a long time, while the similar infusion made from adults transformed it almost immediately. He made similar experiments on the enteric juice, though with less satisfactory results, but some of them appeared to show him that the intestine transformed starch at an earlier age than the pancreas. Sossino himself raises the question how far we may reason here from analogy.

Korowin,³ at the children's clinic at St. Petersburg, made examinations that, in connection with those of Sossino, appear to be of more value than either alone, inasmuch as both reached somewhat the same result, the one through children who had died sick, the other through animals who had died well. Korowin tried to turn starch into sugar by means of the pancreas of children who had died of different diseases, mostly of the chest and intestines, and who were examined at different periods after death. He found no diastatic action during the first month, a little during the second, enough for quantitative analysis at the end of the third, and the quality fully developed at the end of the first year. His report, which is valuable, would, I think, be more so if he had divided his intestinal and non-intestinal diseases into two groups.

I am indebted to the note-book of Dr. G. M. Garland for an account of examinations by Dr. Hans Wegschneider, who succeeded in converting starch into sugar by means of the fresh faeces of sucklings. He sometimes got a reaction in an hour, a strong one in twenty-four hours. These experiments agree with those of Sossino on the infant intestine. The value, however, of Sossino's experiments on the intestine is diminished by the observation of Paschutin,⁴ that the mucous membrane of other organs in dogs has diastatic power.

Beside these experiments in cooking starch in sections and in infusions of organs, there remain those

made directly upon the intestinal contents of young starch-fed children. In twelve autopsies, made by M. Guillot, of children dead from different diseases, he found that both the small and the large intestine contained starch, as shown by a deep blue with tincture of iodine. I believe that there is a fuller account of these autopsies than I have been able to find, but that the children were quite young appears probable from their being quoted by Valleix⁵ in an article based on observations on the newly born. Zweifel⁶ examined the body of a seven days' child, born at term, and fed exclusively on Nestlé's *kindermehl*. The contents of the stomach were slimy and swollen, containing sugar and especially starch, which through its swelling had pressed the stomach out of place. The large intestine contained only unaltered starch. It would seem from this report that the child must have been liberally supplied with it, but it is to be observed that the remaining parts of the diet were disposed of. One analysis⁷ of the *kindermehl* shows sugar, fat, salts, etc., and thirty per cent. starch and dextrine. Other analyses give little starch.

Of course, in any experiments made at an autopsy, we are dealing with the organs of the sick, and it is always a fair question how much the sickness has altered the conditions. While we may have to wait a long time for the combination of a group of early autopsies in starch-fed babies, dead from violence, yet meanwhile we can examine the faeces of living children.

Prospero Sossino made ten such examinations, as follows:⁸ (1.) Sick child of three months. Nestlé's *kindermehl*. Starch shown in faeces by iodine and microscope. (2.) Enlargement of glands of neck, atrophy and diarrhoea at six months. Diet lactose. No starch in faeces. (3.) Well except for club-foot. Three months. Lactose. Strong blue color with iodine. (4.) Condition not stated. Fifteen months. Beef tea and lactose. No starch in faeces. (5.) Convalescent from pneumonia. Five years. Starchy food. A trace of starch in faeces. (6.) Erythema and rickets. Three years. Milk and starch. Faeces afford strong evidence of starch. (7.) Condition not stated. Three months. Mother's milk and bread. Faeces contain starch. (8.) Condition not stated. Twelve months. Milk and flour. No starch in faeces. (9.) Condition not stated. Age four and one half months. Groats, corn flour, and milk. Starch abundant in faeces. (10.) Condition not stated. Ten months. Beef tea, yolk of egg, milk, and twice a day one teaspoon of arrowroot. Faeces contain a little starch.

It is interesting to notice that the pneumonia-convalescent and the patient with empyema and rickets did not digest all their starch, though far beyond the age at which Korowin's examinations would lead us to expect that they would; also that the ten-months' child, health unknown, failed to dispose of two teaspoons of arrowroot, half at a time, and to observe that he was taking not merely arrowroot, but a mixture of four different articles.

The most valuable cases of the series, as bearing on digestion under ordinary circumstances, are the five-

⁴ Centralblatt für die medicinischen Wissenschaften, 1870, s. 560, 577.

months' boy, well but for club-foot, who passed unaltered starch, and the three children of twelve to sixteen months, of whom one at least was ill, who digested it.

During the past two weeks I have tried to repeat these experiments, but being unwilling to be the means of making young children eat starch, and not caring to experiment except with well children, have but one case to report. This is a perfectly healthy boy of eleven months, having five teeth, and eating Indian and oat meal, bread, cracker, and milk. I have repeatedly examined his feces with iodine, always with a negative result.

It seems to me that in examining feces for this purpose, either sick children should be rigorously rejected, or at least they should be arranged in a separate group. Such statistics, though less numerous, would be more valuable. It seems to be shown by this group of experiments that while there may be some question as to what is the earliest age at which starch is digested, it certainly is, in some children, in very small amount before the third month, and that as a rule children cannot digest it before the second year, perhaps later, to the same extent that adults can. These results seem to be reached most definitely by the experiments of Korowin. We may get still more definite ideas with increased knowledge of the infant intestine. The examination of recent infant feces seems also a promising field of inquiry. But we can never arrive at exact results owing to what has been called "the difference of physiological age" in children at the same period after birth,—a difference perfectly well recognized. Compare, for instance, the case with which this paper was begun; a year old child, with two teeth, who passed Ridge's food unaltered through the bowel, with the other boy of eleven months, who had five teeth, and whose feces gave no reaction with iodine, in spite of bread, cracker, and meal. It is well known that many physicians are in the habit of ordering starch in small quantity with milk, and getting good results, and it has been shown by Dr. Putnam¹ that starch so given may make milk more digestible without being itself digested. It seems to be desirable, where this practice is followed, to have it thoroughly understood by the attendants that they are dealing, not with a food, but a drug, and a powerful drug, in order to hinder such abuse from ignorance as in the reported case in which starch was not recommended at all.

SLIGHT LACERATIONS OF THE PERINEUM.²

BY G. H. LYMAN, M. D.

FOR some years past I have been more and more impressed by the frequency of perineal ruptures,³ and with the added experience there has come an increased sense of the importance of the complex symptoms,—the serious derangements in the health of females, induced by these diseases, even when they are apparently but trivial,—and I therefore am glad of the opportunity offered me to ask the attention of the society to the subject.

The question of the need or the propriety of sutures for incomplete lacerations at the termination of labor is often raised in our societies and journals. Many excellent and experienced obstetricians believe that it is only necessary to tie the patient's knees together, and the rent will heal; and so it does; but after many years of observation, in private and hospital practice, I am sure that I have never seen a single instance of union by first intention where sutures had not been used, but always have found the healing to be by granulation, with more or less extensive cicatricial surfaces. It will be claimed by no one when the rupture is of any extent, through the perineal body, for instance, that it is unimportant; but the belief is quite common that a slighter laceration is really of no consequence whatever, and that neither patient, husband, nor physician is ever the wiser for it. As to the last of the three, this would seem to be pretty generally true; but there are few husbands who are not aware of the difference, though they may not proclaim it publicly, and fewer wives who are not sufferers from it. It is, indeed, a fundamental error, and one which, like many others connected with obstetrical practice, it is of great importance to have corrected. No laceration extending beyond the fourchette sufficiently to leave a recognizable cicatrix is unimportant, for no such lesion is without injurious results in many ways, and it really is high time that the practice now so generally considered satisfactory should be reviewed. The remedy for the lesion is so simple, and the consequences of its neglect often entail so much suffering, that to me it appears absolutely criminal for any obstetrician to leave his patient without applying it.

It may seem that I am attaching altogether too much importance to a lesion which by many is regarded as the normal condition of women who have borne children; but a very little reflection, certainly if fortified by more of practical observation, will, I feel confident, induce such to change their views. I say practical observation, and here comes in the very difficulty, the real reason, as I believe, for the indifference and disbelief. I would ask gentlemen, especially those engaged in extensive obstetric practice, how often they are permitted, or even if permitted how often they think it worth their while, to examine the perineum a month or two after labor. The answer of most of them will doubtless be, never. The so-called trifling aches, ails, and discomforts which so often follow ordinary childbirth are supposed by most women to be the necessary results of the trial which they have recently undergone; and even when, after the lapse of a considerable period, their medical adviser is consulted, the chances are very great that the cause of the reflex symptoms is either overlooked or ignored; the patient is comforted with the assurance that she is only a little run down, and only needs a little tonic treatment. Those, however, who, either because of special attention given to gynecology, or from the opportunities which large hospital practice afford, have daily occasion to examine freely know full well how much of discomfort and even positive suffering may be traced directly to this cause, or, if disposed to doubt, will, I am sure, soon confess their error, after their attention is more decidedly directed to it.

What is the use of the female perineum? Manifestly to give support as a floor to the contents of the pelvis, the bladder, the rectum, the uterus, and ovaries. This would seem almost too absurdly elementary to re-

¹ Boston Medical and Surgical Journal, August 1, 1873, page 81.

² Read before the Boston Society for Medical Improvement, December 8, 1879.

³ Estimated by Schroeder as occurring in over one third, and by Olshausen in over one fifth, of all parous women.

peat here, until the farther question arises, How much of this floor may be weakened or destroyed without injurious results? My answer to which is, *Not a single line.*

If the rupture extends into the rectum, no one thinks of questioning the unfortunate results; if it extend only through the sphincter vaginae, a certain number content themselves with the idea that the woman is lucky that it went no farther, and that no great difficulty need be apprehended; if the rupture be still more trifling, involving either none at all or only a portion of the fibres of the sphincter, hardly any one of those I have mentioned would give it a second thought.

It is this tendency to ignore the importance of these slighter ruptures which I would especially protest against. The unpleasant results are of course proportionate to the extent to which this barrier to the pelvic outlet is weakened; but what I wish to insist upon is that no part of that support, however slight it may seem, can be removed without weakening in a corresponding degree the floor itself, and thereby originating nervous and circulatory disturbances. The general relaxation of the vulvar orifice and subinvolution of the vagina which are present after the most perfectly normal labor are in themselves quite sufficient; but when to these there is added a rent which has healed not by union, but by cicatrization, the difficulty is increased to a manifest degree.

The more common results which may ensue, if enumerated somewhat in the order of their gravity, and more or less likely, in proportion to the extent of the laceration, are, primarily, septicæmia, and, secondarily, sterility, cystocele, rectocele, and prolapsus, with consequent derangements of the pelvic circulation, as shown by endometritis, cervicitis, cystitis, and leucorrhæa; imperfect coition, pruritus, vaginal flatus, and extensive reflex neuralgic irritation from the cicatrices. This is a formidable list, but it might be extended without exceeding the reality. Of course, all do not occur, or many of them, perhaps, in every case, but in the majority of cases one or more of them are sufficiently common. In many patients a very trifling laceration, as may be readily demonstrated by placing the patient upon her back with her knees flexed, will allow both anterior and posterior vaginal walls to prolapse sufficiently to separate the labia and expose the whole length of the urethra, without any manual interference. This of course cannot happen without more or less of dragging upon the uterus; any descent of the uterus must involve interference with the pelvic circulation, and its sequences of endometritis, cervicitis, and leucorrhæa. If the laceration involves the vaginal sphincter, coition is necessarily imperfect, the seminal fluid is less likely to be retained, the muscular depression of the clitoris upon the male organ is interfered with, to the annoyance and disappointment of one of the parties at least, from unsatisfied excitement of a nervous system already sufficiently hyperæsthetic. In the slighter lacerations, the most common difficulty results, perhaps, from the presence of cicatricial tissue at the posterior commissure. In simple lacerations of the cervix uteri, this has been proved to be the cause of intense neuralgia from the strangulation of nerve fibrils in the cicatricial tissue, by the prompt relief which has followed the excision of the cicatrices for the closure of the separated lips of the cervix. Every surgeon is familiar with similar cases of reflex action. Even deep etherization will sometimes fail to subdue

entirely the spasmodic movements caused by the pressure of a Sims's speculum upon these cicatrices at the posterior commissure, as I have often had opportunities to observe. This being so, it is not to be wondered at if the unfortunate subjects of even a slight neglected laceration should suffer at times from reflex neuralgia of one or all of the pelvic viscera.

The subject might be elaborated much farther, especially in the direction of its mental phenomena, but my object has been simply to call your attention to the subject. That object will be attained if I succeed in awakening any interest in what I am forced to believe is a very serious mistake,—the frequent neglect of obstetricians to inspect thoroughly the perineum immediately after labor, and if there be found any laceration, however slight, to introduce deeply a sufficient number of sutures to retain the edges in contact, exclude the lochial discharges, and allow the parts to heal by first intention instead of by granulation, with its necessary sequel, cicatricial induration. It is but the work of a moment, from the benumbed condition of the parts almost painless, and may save one of the parties much severe suffering, and both of them much of subsequent annoyance.

Elsewhere this subject is attracting a good deal of attention, and those who may care to pursue it farther will find an admirable paper by Dr. Reamy, of Cincinnati, in the last volume of Transactions of the American Gynecological Society.

RECENT PROGRESS IN OBSTETRICS.

BY W. L. RICHARDSON, M. D.

Pilocarpine in Obstetric Practice.—During the past two years obstetricians have been using pilocarpine quite extensively in obstetric practice. The results have been in some cases very marked, often times to the advantage, but occasionally to the disadvantage, of the patient. Among the most valuable experiments which have been reported are those of Dr. Marti, who has arrived at the following conclusions¹ after many experiments on pregnant women and animals. He has found that subcutaneous injections of pilocarpine have had only negative results when used on pregnant women or animals. In cases, however, in which the female or animal is already in labor or near labor, subcutaneous injections of this drug have had the power of setting up uterine contractions. When such contractions have occurred, they have usually appeared very soon after the injections were made. At first they increased in frequency, but the contractions soon became stationary, and then suddenly altogether ceased. He was convinced that pilocarpine was powerless to produce premature labor, but did have more or less influence on the contractility of the uterus when administered subcutaneously at the end of gestation or during labor. He found, however, that the contractions produced by the use of pilocarpine were not very strong, and in some cases failed to effect a delivery of the fetus.

Dr. Bidler² has seen most favorable results follow the use of pilocarpine in cases of marked œdema of pregnancy, while prescribing it for patients suffering from œdema of the face, extremities, and labia; he has

¹ Le Progrès méd., May 10, 1879.

² Medical Times and Gazette, September 6, 1879.

never seen uterine pains excited by its use, although the oedema very rapidly subsided.

Dr. Sönger has reported¹ three cases in which he ordered injections of pilocarpine for the relief of puerperal eclampsia. The convulsive attacks were relieved, but almost immediately after the injection there were observed most marked symptoms of suffocation, owing to the patient's inability to swallow the amount of saliva and mucus resulting from the use of the pilocarpine. He has come, therefore, to the conclusions that while this drug is most valuable at the outset in cases of eclampsia, and when the convulsive seizures are slight, it is unquestionably contraindicated in all cases in which there are symptoms of impending coma.

Anatomical Proof of the Existence of the Cervix Uteri during Pregnancy.—Dr. Sönger (Leipsic) has contributed a most valuable paper² on the existence of the cervix uteri during pregnancy. After going carefully over the previous discussions on this subject by other writers, and especially criticising the views of Küstner and Bandl, Dr. Sönger gives the detailed account of an autopsy made on a patient who had died suddenly during an eclamptic seizure at nearly the end of the ninth month of her pregnancy. Caesarean section was at once performed by Professor Credé. The plicae palmatae of the cervical mucous membrane were intact, and the fetal membranes, covered with the decidua, ran down close to the edge of the mucous membrane of the cervix. There was a well-defined line marking where the cervix ended and where the lower segment of the uterus began. No intermediate space could be found, such as Bandl and Küstner insist lies between the inner os and the ring of Müller. The anatomical appearances in this case supported strongly the view that the cervix uteri persists during the whole of pregnancy, or at any rate until towards the very end. A careful microscopical examination in this case subsequently confirmed this view, and positively contradicted the old theory that the cervix is gradually taken up towards the close of pregnancy, and in that way helps to enlarge the lower segments of the uterus. There was, however, found in this case no elevated ring at the junction of the cervical mucous membrane and that of the lower uterine segment, but the two merged directly the one into the other. The dimensions of the vaginal portion of the cervix were, namely: anterior wall, 1.5 centimetres (.6 inch); posterior wall, two centimetres (.8 inch); breadth of the upper part of the cervix, 2.5 centimetres (one inch).

Dr. M. Thiede (Berlin) claims that his observations have shown conclusively that the ring of Müller and the inner os uteri are really identical. He has observed in autopsies the decidua vera attached along the line of the upper edge of the cervical canal. Microscopically examined, he believes that it is always possible to distinguish the lower uterine segment from the cervical mucous membrane.

Ligation of the Umbilical Cord.—The question as to the proper time for ligating the umbilical cord, which Dr. Buchli raised in 1875, has given rise to a great deal of discussion and some very valuable and practical experiments. Exactly how much extra blood the fetus gains, if the ligation of the cord is delayed, is still a disputed point, Professor Zweifel, of Erlangen, claiming that the loss amounts to one hundred grammes,

while Meyer, of Copenhagen, gives as the result of his experiments a loss of only sixteen grammes. The truth probably lies between these two extremes, as the observations of Dr. Hofmeier, of Berlin, would lead us to believe. By means of a carefully adjusted weighing machine he was enabled to observe the gradual gain in thirty-two cases, the infants being placed on the scales the moment they were born, and the balance being carefully watched until the cord ceased pulsating. He gives as the result of his experiments an average gain of 63.6 grammes.

Schüicking claims that this surplus blood is needed by the child, inasmuch as by the first inspiration of the child the blood is drawn into the thorax, and the blood-vessels outside of the thorax are necessarily left empty. With this idea he strongly deprecates allowing a hæmorrhage from the funis with a view of relieving the asphyxia of a new-born child.

It is well known that children at first lose weight after birth. Hofmeier, of Berlin, found that children whose cord was tied late lost one per cent. less of their weight than other children, and that they also began to gain in weight from one third to one half a day sooner. Meyer, however, claims that these results only obtain in children weighing over three thousand five hundred grammes.

Riehemont agrees with Schüicking as to the value of the blood contained in the placental vessels for the perfect establishment of the infantile circulation, and therefore deprecates strongly the advice given by some writers who favor the permitting of hæmorrhage from the funis with a view of relieving the threatening asphyxia. In such cases the flow of blood from the placenta towards the child should be encouraged, and any cutting or ligation of the umbilical cord should be delayed as long as possible. He also claims that by so doing the subsequent removal of the placenta is facilitated.

Dr. Porak, in an admirable article on the jaundice of new-born children, takes the ground that the affection is, as a rule, of hæmic origin, and that those children are more apt to have it in whom the funis has been tied late, — a fact which he thinks strongly corroborates his idea of its being due to a hæmic origin rather than to its being dependent on any hepatic obstruction or on any peculiar condition of the hepatic circulation.

Dysuria in Childbed.—Engle gives³ the result of his study of 1325 cases in which there was a retention of urine after delivery which lasted for a longer or shorter time. Of these, 600 were primiparae and 725 multiparae. In 35.3 per cent. of the primiparae it was necessary to use the catheter, while in only eight per cent. of the multiparae was it necessary thus to draw off the water. This dysuria he ascribes to the presence of lacerations which so frequently occur in first labors. No matter how slight the laceration, it will give rise to an inflammatory process which extends to and irritates the sphincter fibres, and thus causes a tonic spasm. Later, when the inflammatory stage is passed and the laceration has become an ulceration, the spasm ceases. In ninety per cent. of the cases examined he was able to trace a direct relation between the spasm and a laceration. In 212 cases of primiparae the laceration was near the urethra in 28; in the bubi of the urethra in three; the urethra and perineum

¹ Archiv für Gynækol., xiv, 3.

² Archiv für Gynækol., xiv.

³ Centralblatt für Gynækol., 1878, 25; Archives of Medicine, April, 1874.

were together affected in 16; there were ruptured perinaei in 103; condylomata and syphilitic ulcerations were seen to be more or less torn in 10. In only 22 could no laceration be found. Among the 54 multiparae 16 had a lesion near the urethra, 23 a laceration of the perineum, five condylomata or syphilitic ulceration, and in 10 nothing could be seen.

The treatment was such as would tend to reduce the spasm. Pieces of ice were introduced into the vagina, and the meatus was irrigated with douches of warm water. The passage of large-sized bougies into the urethra was often very useful. While investigating these cases Dr. Engle observed that a distended bladder had considerable influence on the involution of the uterus, and also predisposed to secondary hemorrhage. In the 278 cases of dysuria examined there were 52 in which there was more or less secondary hemorrhage.

Condition of the Uterus at the Placental Site.—Dr. George Roper calls attention¹ to the fact that, no matter where the placenta is attached, there is always an induration and thickening of the uterine tissue at the site of its attachment. In cases of placenta previa there will be found a well-marked induration around the entire circumference of the internal os uteri. In cases where there is only a partial placenta previa the obstetrician can easily detect this induration by comparing the feel on the side to which the placenta is attached with that on the opposite side. The result of this induration is to render that part of the uterus unyielding; and hence Dr. Roper calls the notice of the profession to the necessity of using great care in effecting any forced delivery in such cases of placenta previa, the tissue being much more liable to serious lacerations than in other cases where there is no low placental attachment, and no induration of the tissues.

Hospital Practice.

BOSTON CITY HOSPITAL.

CASES TREATED BY THE LISTER METHOD: SERVICE OF DR. GAY.

REPORTED BY W. H. HOLMES, M. D., HOUSE SURGEON.

Buboes.—CASE I. Samuel W. entered the hospital August 22, 1879, with an indurated mass in his left groin the size of a hen's egg. There was a creamy discharge from the urethra; there was no sore to be seen on the penis, nor could any history of infection be obtained. A blister was applied over the bubo, but with no beneficial effect. August 31st, Dr. Gay made an incision four inches long and removed a mass of indurated and enlarged glands. Full "Lister" precautions were observed, except that on one occasion a non-disinfected hand was brought into contact with the wound. Then carbolyzed silk sutures were put in, a drainage tube inserted, and a Lister dressing applied. On the fifth day after operation, the scrotum and penis were attacked by phlegmonous erysipelas, which lasted about two weeks. At no time did there appear to be any erysipelas about the edges of the wound. Sutures and drainage tube were removed on the tenth day. No pus was seen until the seventh day, and there was only a very small amount during the progress of the case.

The Lister dressing was omitted on the fifty-sixth day, having been changed seventeen times. On four or five occasions only were the dressings stained through when they were changed. The wound had healed at the end of the eighth week.

CASE II. Nicholas Q., aged twenty-three, was admitted to hospital August 25, 1879, with a bunch of indurated glands in the left groin. Three weeks before entrance he had had suspicious connection, but gave no history of any sore on the penis. October 5th, Dr. Gay made an incision three and a half inches long over the bubo and removed a mass of suppurating glands. The surrounding tissues were boggy and infiltrated with pus. The operation was done strictly according to Lister's method, and carbolyzed gauze dressings were applied. On the evening of the same day, the patient had a chill, and the temperature reached 106° F. The dressings were changed, and the temperature fell to 100° the next morning, going above that point only three times in the progress of the case. The sutures and drainage tube were removed on the fifth day, as the discharge, which had been very slight, had nearly ceased. Lister dressing was omitted on the fifteenth day, as at that time there existed only a small superficial ulcer, which had healed on the twentieth day. The dressings were changed eight times, being stained through only once.

CASE III. Edward M., aged thirty-four, entered hospital August 26, 1879, with a hard chancre on the left side of the prepuce, and a large indurated bubo in the left groin. The patient last had sexual intercourse three months before admission. September 5th Dr. Gay made an incision four inches long, and removed a large mass of indurated glands under full Lister precautions. On the seventh day, the wound was nearly healed, and the sutures and drainage tube were removed. A long narrow sinus remained, which did not head till the twenty-second day, when the Lister dressing was omitted. Dressings were changed sixteen times, being stained through only two or three times. Secondary syphilitic symptoms appeared on the twentieth day after admission, and were successfully treated by the protiodide of mercury, half a grain *ter die*.

In all the foregoing cases the dressings were kept in place by means of elastic webbing applied as a spica bandage.

Abscesses.—CASE I. Dennis C., aged thirty, entered hospital September 22, 1879, with a large fluctuating tender swelling in the left lumbar region. September 26th Dr. Gay made an incision one and a half inches long into the swelling under carbolic spray, which gave exit to about a pint of thick creamy pus. The finger entered the abscess its entire length over the crest of the ilium backward and downward toward the lumbosacral articulation. A diagnosis of periostitis of the crest of the ilium and perhaps of the transverse processes of the lower lumbar vertebrae was made. A Lister dressing was applied, which was stained through on the fourth day after operation and was then renewed. There was scarcely any discharge of pus after the first emptying of the abscess. The Lister dressing was omitted on the thirtieth day, having been changed nine times. No fever followed the operation, nor any constitutional symptoms. November 30th, a probe passed three inches into a sinus. A dressing of carbolyzed gauze wet in carbolic acid, one to forty, applied without spray, was put on about every fifth day. There was very little discharge and that perfectly healthy.

CASE II. Timothy D., aged thirty-five, entered hos-

¹ London Lancet, October 25, 1879.

pital November 1, 1879, with a large, red, tender, fluctuating swelling, just above Ponpart's ligament, on the right side. November 2d, Dr. Gay made an incision under spray and with antiseptic precautions, evacuating nearly a pint of pus. A drainage tube was inserted and gauze dressings were applied. A probe was passed in for ten inches. No dead bone was discovered. On the twenty-eighth day the dressings were omitted, as the opening had healed; they were changed nine times. The discharge at first was very profuse, necessitating two dressings daily, but became much less after the fourth day. On the second day, the temperature reached 102°; on the third day, it fell to the normal point and did not again rise. At present (November 30th) there is no fluctuation over the seat of the abscess, and the resonance or percussion is tympanitic. The wound remains closed.

Amputations. — CASE I. On October 16th, the left arm of Francis F. was drawn between two rollers, which crushed the forearm, and the lower third of the upper arm. The same day Dr. Gay amputated about four inches below the shoulder joint. After the removal of the tourniquet there was considerable capillary oozing, which was checked by the application of hot water. During, and after the operation, the stump came several times into contact with the sheet, and with the patient's shirt. With these exceptions the operation was performed with full antiseptic precautions. A drainage tube was inserted and carbolized gauze dressings were applied. The sutures were removed at the end of the first week; the dressings were omitted at the end of the second week, having been changed six times; at this time the stump was healed with the exception of a small sinus. There was some discharge of pus during the first fortnight, and it had at times a disagreeable odor. On the thirtieth day the sinus mentioned above had entirely healed, and the stump was a good one.

[The amputation was made through tissues which had been much damaged at the time of the accident, yet no sloughing followed. The hemorrhage had been so profuse, before the patient's arrival at the hospital, that his pulse was weak and irregular, his countenance pale, and he was becoming restless. An eighth of a grain of morphine was given subcutaneously, and in an hour he had rallied sufficiently to justify the operation.]

CASE II. In October, 1878, Frank S., aged twenty, froze both his feet and ankles so badly that spontaneous amputation took place in the right leg about one inch above the malleoli, and in the left at the junction of the middle and lower thirds of the leg. Patient entered hospital September 29, 1879. The tibia on each stump projected an inch beyond the skin, and was covered by pale, flabby granulations. October 3d, Dr. Gay amputated both legs by the skin-flap method four inches above their ends. A drainage tube was inserted into each leg, and the details of the antiseptic method were observed. The right stump had healed on the nineteenth day, and the dressings were omitted, having been changed ten times. There was only a slight amount of pus from this stump. The dressing on the left leg partially slipped off the afternoon after operation, and on the third day there was an abundant discharge of pus. The Lister dressing was continued, being changed daily. The left stump was healed on the thirtieth day. The temperature was 100.5° the second day, but did not again rise so high, and after

the sixth day was normal. The stumps were of excellent shape, and firm.

Hæmatocele. September 4, 1879, Timothy C., aged twenty, presented himself at the hospital with a hydrocele of the right tunica vaginalis, which was tapped in the usual manner. When the sac was nearly evacuated, blood began to show itself in the stream of liquid, the canula was withdrawn, and rest in bed advised. The flow of blood continued into the sac until there was a swelling in the right side of the scrotum two inches in diameter. On the eighth day after this accident, Dr. Gay made an incision one and a half inches long into the tunica vaginalis, and let out about ten ounces of fluid blood and clots. The operation was done under carbolic spray, a drainage tube inserted, and gauze dressings were applied. The dressings were retained in place by a gauze bandage snugly applied about the base of the scrotum, and by a double T bandage. The wound was healed at the end of the second week. No pus was present during the healing. The dressings were changed daily. The drainage tube was removed on the ninth day.

Floating Cartilages in the Knee Joint; Removal. — Frank D., aged twenty-six, entered hospital September 19, 1879, to receive treatment for floating cartilages in his knee joints. In his right knee was one of these bodies of large size which had never given any trouble; no operative interference was advised. In the left knee there were three, which occasionally gave rise to much pain. There was considerable effusion in the joint, and the patient was lame. The left leg was put upon a ham splint and the patient put to bed. At the end of a week Dr. Gay made a small valvular incision, an inch and a half below the inner and lower angle of the left knee joint, and by pushing a narrow Sims knife up underneath the skin, made an opening into the synovial cavity sufficiently large to enable him to press out three loose cartilages, the largest of which was three fourths of an inch in diameter, and the smallest about half of this size. They were smooth, irregular, and very hard. The operation was a thorough "Lister." Three sutures were inserted, and the limb was replaced upon the ham splint. There was union by first intention; no pus; no pain; no opiates required; dressings changed twice. The patient was well in ten days. The knee joint was of nearly the normal size, had good motion, and there was no lameness.

[*Remarks.* In addition to the above cases, many minor operations were performed under antiseptic precautions with very satisfactory results. Although supuration was not wholly avoided in all of the cases, yet practically it was slight or moderate, never profuse; oftentimes there was no constitutional disturbance whatever; the wounds were usually sweet and free from any disagreeable odor; and recovery was reasonably quick.

During a recent visit to London, I was surprised at the boldness with which certain operations were performed under the Lister method. At Guy's Hospital, I saw Mr. Bell cut down upon a recently fractured patella, saw off the rough surfaces, and wire the fragments together. It was by no means an easy matter to bring the fragments into apposition, even after freely dividing the rectus muscle subcutaneously about four inches above the joint. Mr. Lister and Mr. Henry Smith have both performed this operation, and claim to have got good results.

We saw the following cases in Mr. Lister's wards, all operated on and treated successfully by himself under antiseptics, and all free from suppuration or general disturbance: Amputation at the hip joint; knee joint laid open for acute suppuration, the wound healed, and some motion remaining in the joint; excision of the wrist; iliac abscess following peritonitis, a most desperate case; lumbar abscess due to Pott's disease; section, through free incisions of the right tibia and fibula and the left femur for rachitic deformity, making a double compound fracture.

Another case was shown of a man whose knee joint was torn open by an injury. Ten hours after the accident Mr. Lister syringed out the cavity of the joint with a solution of carbolic acid (one to twenty), and washed the dirt and gravel from the wound with carbolic acid and rectified spirit (one to five), and treated it antiseptically. The patient did well, the wound was healed, and at the end of seven weeks there was little swelling and some motion.

We were assured that the rule in Mr. Lister's operations was no pus, except, perhaps, a little from superficial granulations, and no constitutional disturbance of any consequence. He claims that the blood-clot becomes organized, and that the processes of granulation and cicatrization take place without suppuration.

I saw no unfavorable cases in his wards, and the house-surgeon said that the antiseptic cases were never attacked with erysipelas, but that patients in the other wards, treated by the old methods, not infrequently suffered from this disease.

All wounds in Mr. Lister's wards, except of the head and rectum, are treated strictly according to his method, and he is very careful to have all minutiae properly looked after, as it is the little things that make the system perfect. The spray is large; carbolized solution used in abundance; hands clean, thoroughly disinfected, and kept so, as well as the instruments; drainage tubes everywhere; gauze bandages instead of the cotton roller; elastic webbing to retain dressings in groin and perinaeum; and the dressings are changed as soon as the discharge stains through, or every week at the farthest.

Whatever may be thought of Mr. Lister's plan, certainly no one can visit his patients and listen to his most interesting remarks without catching something of that enthusiasm, and sharing somewhat in that faith in antiseptics which has so justly made his name famous all over the world. (G. W. G.)

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

T. M. ROICH, M. D., SECRETARY.

SEPTEMBER 27, 1879. Fifty-two members were present. DR. CALVIN ELLIS in the chair.

Cystocele.—DR. WILLIAM H. BAKER read a paper entitled *Cystocele, its Causes and Treatment*. He first defined the lesion, and then spoke of the diagnosis and causes of the disease, stating that the cases met with from other causes than childbirth were rare, and that the prime factor in the production of cystocele was the want of integrity of the perinaeum, caused either directly by rupture, or gradually by a loss of

tone of the vagina and perinaeum from repeated parturition. In speaking of the treatment, which he divided into operative and non-operative, he stated that the operation was contra-indicated (1) when the case was acute or of recent origin; (2) when there was any inflammatory action present (as peri-uterine cellulitis or peritonitis); (3) when there was renal disease, for this operation almost invariably occasions some temporary cystitis, which in such instances is very likely to extend to the ureters and pelvis of the kidneys, thus greatly increasing the danger of the operation; and (4) when the patient was too old. He also said that the operation for cystocele could not, however, be considered complete until the integrity of the perinaeum was insured. Where operative procedures are uncalled for, he mentioned the treatment of those acute cases which are caused by excessive muscular effort by rest, astringent injections, and care that the bladder was not distended. He also spoke of the inadequacy of pessaries, either the ring pessary or Hodge's, but favored in certain cases the use of Emmet's Hodge pessary with septum, remarking that it acted by means of its suction power.—DR. WING inquired if the operation needed the use of a supporter afterwards.—DR. BAKER replied that it did when the uterus was not of normal size.—DR. WING remarked that in his experience cystocele often came from subinvolution of the uterus, and that in six cases which he had seen during the past year it had been relieved by supporters; in three of these cases there existed cystocele, rectocele, and procidentia, all of which the supporter appeared to relieve. Where there is absence of the perinaeum the patient can remove and replace the supporter, while if the perinaeum is sewed up sufficiently to act as a support she cannot accomplish the removal.—DR. BAKER said that it was difficult to apply a Hodge pessary when the perinaeum was weak, as the action of the pessary depends on the integrity of the perinaeum.—DR. WING replied that he could not agree with Dr. Baker on this point, as we often see the successful action of the Hodge pessary where the perineal body is absent. Dr. Wing also remarked that he did not believe in the suction power of the pessary spoken of by Dr. Baker as giving support, as the suction power is downwards.—DR. GARLAND said that he did not understand how the pessary in question could support the parts above it by virtue of any suction. When two bodies are held together by atmospheric pressure the resistance which they offer to any force striving to separate them is called suction. The suction force, however, comes into play only when an attempt at separation is made. Thus in the case of Dr. Baker's illustration of the boy's sucker,—a piece of leather on a brick,—the suction becomes evident only when the boy tries to remove the leather from the brick. Dr. Baker thinks that suction is demonstrated by the non-protrusion of the bladder when the patient bears down. Bearing-down efforts, however, do not tend to separate the bladder from the pessary, but they crowd the former down upon the latter, and therefore no resistance of suction can be called out in this way. If the pessary under these conditions still holds the parts in place it must do so in the same manner and on the same principle as a Hodge's pessary. Indeed, suction between the pessary and soft parts would actually tend to drag those parts down by reason of the weight of the instrument, if the latter were not otherwise supported. Dr. Garland said that if the brick, previously men-

tioned, were placed in the ceiling of the room he could not see how the piece of leather underneath could prevent that brick from falling merely by virtue of the suction between them. — Dr. C. P. PUTNAM thought the theory of atmospheric pressure, which is what is meant by suction, was applicable to this case. The soft walls of the bladder tend to bulge at the middle part, while the sides are sustained by firmer tissues. If this bulging part is replaced and a flat plate applied against it, the bulging is prevented so long as no air can get in between the edges of the plate and the bladder. The weight to be overcome is the middle part of the bladder, which tends to fall, and it is held up because fixed by atmospheric pressure to the edges, which are held up by other parts around.

Registry for Nurses. — Dr. PUTNAM also spoke in regard to the registration of nurses, and mentioned how important it was to have a reliable directory. He requested members to send the names of such nurses as they considered proper for the purpose to the library, to Dr. F. C. Shattuck, or to himself.

THE RHODE ISLAND MEDICAL SOCIETY.

THE regular quarterly meeting of the Rhode Island Medical Society was held in Providence, on Wednesday, December 17th, the president, Dr. E. T. CASWELL, of Providence, in the chair.

Dr. FULLER, surgical interne at the Rhode Island Hospital, exhibited to the society several microscopical sections prepared by himself from cases occurring at the hospital. They included specimens of sarcoma, fibroma, epithelioma, and the head of a tenia.

Dr. Sylvanus Clapp. — The secretary read a biographical sketch of Dr. Sylvanus Clapp, of Pawtucket, who died in June, and who was at the time of his death one of the leading physicians of the State. He was elected to membership in this society in 1842, and served as its president from 1864 to 1866. He was a member of the board of censors at the time of his decease, having been re-elected to that office a few days before his death. He was one of the consulting surgeons of the Rhode Island Hospital from the first establishment of that institution, and served as visiting surgeon during the last quarter of the year 1874. He was appointed consulting physician to the Butler Hospital for the Insane in 1878. He took an active part in establishing the Pawtucket Dispensary, and was president of its board of directors. In 1870 he received from Brown University the honorary degree of Master of Arts.

Scarlatina. — Dr. C. H. LEONARD, of Providence, read a paper upon the treatment of scarlatina. He believed in the propagation of the disease by contagion, and advocated a rigid isolation of patients and thorough disinfection of the premises and of all articles used about the patient. For treatment he would rely upon abundant nourishment, perfect quiet, good ventilation, and skillful nursing. He recommended tonic remedies, and spoke strongly in favor of the inhalation of oxygen gas.

New Members. — Upon recommendation of the board of censors, the following persons were admitted to membership: Dr. Henry Stillman, of Cumberland, and Dr. Harriet G. Belcher, of Pawtucket. The latter is the third female physician who has been admitted to the society.

Medical Law. — The committee upon the registration of physicians presented a report recommending that a committee be appointed by the president to petition the legislature to enact a law regulating the practice of medicine and surgery in this State. After some discussion the report was so amended as to provide that the committee shall submit to the society at its next meeting a draft of the proposed law. The president appointed Drs. Job Kenyon, H. E. Turner, and L. F. C. Garvin to serve upon this committee.

Library. — Dr. NEWELL, of Providence, from the committee on the establishment of a medical library, made a verbal report, stating that nothing definite had yet been accomplished, although several promises of money and of books had been obtained. — Dr. JAMES R. CHADWICK, of Boston, who was present, gave, at the request of the president, a very interesting account of the establishment of the Boston Medical Library, showing from what humble beginnings it has arisen to its present satisfactory and useful condition. He explained the details of its work in its various departments, and recommended that a course be pursued in this State similar to that which has made the Boston Medical Library so complete a success.

Inebriety. — Dr. W. E. ANTHONY, of Providence, read a paper upon Inebriety considered from a Medical Stand-Point. He recognized two forms of drunkenness, one of which is a vice to be punished, the other a disease which should be subjected to medical treatment. In the one case, the person drinks for the pleasure derived from the effects of the drink; in the other, because the craving and desire is so strong that he cannot help it. The real source of prevention is in an appreciation of what inebriety really is, namely, a form of disease. If domestic effort, professional care, and religious teaching were based upon the theory of disease, and made consistent therewith, a much greater amount of good might be accomplished. The popular idea that in all cases intemperance is a vice must be overthrown, and shown to be fallacious. Between violated law, on the one hand, and domestic sorrow, on the other, the medical profession should stand as a recourse to which both law and the family should be able to refer to procure light and aid.

Sewerage. — Dr. ROBERT F. NOYES, of Providence, read a paper upon The Proper Disposition of Excreta of the Intestines and Kidneys. He considered the amount of excrement discharged daily in this city, the importance of its proper distribution, and the various methods of disposing of it. He spoke of the sewer systems of other cities and of this city. He called attention to the mode of connecting with sewers and of plumbing houses, matters in regard to which much indifference prevails. He proposed the following remedies for imperfect sewer connections: Place two traps in the drain, with a ventilator between, which shall open into the continuation of the drain at a point above all other connections. Never connect a water conductor with a drain. Continue the drain of large size to the highest practical point. The top of the main should invariably be open. Continue a ventilator from just below each small trap placed under water-closets, sinks, set bowls, etc., to the top of the chimney, or end it in the main, above all other connection. Legislation is required, compelling the connection of all estates with the sewer, where practicable, and the doing away with all cess-pools upon such estates. But if cess-pools must

exist, they should be properly built, properly ventilated, and properly taken care of.

The meeting was then adjourned, after which the members were sumptuously entertained by the president at his house.

Recent Literature.

Guide to the Examination of Urine, with Special Reference to the Diseases of the Urinary Apparatus.

By K. B. HOFMANN, Professor at the University of Graz, and R. ULTMANN, Docent at the University of Vienna. From the Second Edition. Translated and edited by F. FORCHHEIMER, M. D., Professor of Medical Chemistry at the Medical College of Ohio, Cincinnati. With Illustrations. Cincinnati: Peter G. Thomson, 1879.

This book of Hofmann and Ultmann, as may be inferred from the title, is not intended to supply the place of the larger and more exhaustive works on the urine. After a chapter on the histology of the urinary organs and a short chapter on the function of the kidneys, the physical characters and chemical constituents of the urine are separately treated, so far as they seem to the authors important for the practicing physician. Then follows in order a description of the various urinary sediments, a chapter on the quantitative determination of the various urinary constituents, and finally an account of the simple, uncomplicated diseases of the urinary organs, in so far as they give signs that can be made available for their diagnosis.

The original requires but little adverse criticism. We do not agree with the authors when they say, speaking of the indican test, that if no violet color is perceived in one or two minutes the indican is not increased; or when they say that waxy (meaning amyloid) casts are characteristic of an amyloid kidney. In speaking of chronic parenchymatous nephritis, the authors mention the presence of granular epithelium in the sediment, but make no mention of distinctly fatty epithelium or fatty casts. The book, however, is a very valuable one, and one that every medical student needs for use in the laboratory, and one that every practicing physician will at some time find of service.

A large majority of medical students and physicians are unfamiliar with the German language. When, therefore, this translation was brought to our notice, our first thought was one of pleasure that so valuable a book had been rendered accessible to all. We are sorry, however, to be compelled to say that we have found much unfavorable criticism necessary. The errors in punctuation are too numerous to mention, and wholly inexcusable. In many cases the meaning of a sentence is made doubtful; oftentimes the true meaning is entirely changed; and in not a few instances a sentence is deprived of all meaning simply through errors in punctuation. Again, no one in reading over this book can fail to notice the carelessness with which the translation has been made. We give a few illustrations as proof of this statement. On page 108 we find the following sentence: "Of the greatest importance for the diagnosis of kidney disease are those structures, disclosing their origin by their form—the uriniferous tubules, and called casts." We think every student would naturally conclude, from

reading the last sentence on page 153, that "pemphigus" is a disease of the kidney, and not a disease of the skin. On page 173 we are told that "we sometimes find pyelitis in *echinococci*;" on page 181 we are told of drawing off urine, "a quantity of which probably has remained for years in the bladder." The following sentence, on page 129, shows either ignorance or the greatest carelessness on the part of the translator. Speaking of obtaining the final reaction in the quantitative estimation of urea, he says, "Add to this mixture a drop of sodic carbonate. If a rusty zone is produced, where the fluids meet, continue to add the test fluid; if, however, this is pale, cease, for the work is completed." We might give other examples, but we forbear.

We also notice a want of that system and preciseness in chemical nomenclature that one would naturally look for in a book of this kind. We find "sodium carbonate" spoken of as "soda," "sodium," and "natrum carbonate" almost in the same breath; we find "calcium chloride" instead of "calcium hypochlorite" or "chloride of lime;" "ammonium, potassium, and sodium," instead of "ammonia, potassa, and soda;" "lead" instead of "lead acetate;" a precipitate composed of "lead," in connection with the test for uroerythrine, etc. We find many errors in printing which a proper revision of the proof-sheets would have rectified. They are too frequent to notice. Errors in the grammatical construction of sentences are also frequent. The use of the word "would" for "should" is noticeable, while occasionally we are treated to a new word, as when the translator says that the "kidneys functionate." The expression to "fish out" in reference to the removal of sediments seems to us an unusual one. The illustrations are mainly good. Those representing casts, however, are not of much value. They do not illustrate properly the appearance of these bodies, and had better have been omitted.

Considering all things, then, this translation has been very carelessly done, and we cannot recommend it. Hofmann and Ultmann is worth translating, and as a consequence is worth translating well. Should the book before us reach a second edition, it is hoped that it will previously receive that careful revision which it requires, and which will render it valuable to every student and practitioner of medicine. W. E. H.

American Health Primers. Eyesight, and How to Care for it. By GEORGE C. HARTLAND, M. D., etc. Philadelphia: Lindsay and Blakiston, 1879. 16mo, pp. 139.

"The object will be to place before the reader such elementary knowledge as is necessary to enable him to understand the conditions under which the eyes must do their work; and to place this knowledge within the reach of all the explanations will be made as simple as possible and the use of 'technical language,' that lion so much dreaded in the path of the general reader, will be carefully avoided."

The author has accomplished his task with a very large measure of success; he has made an interesting and instructive book, and has nowhere fallen into the temptation which seems to beset writers for the laity,—that of trying to increase the popularity of a work by making it in fact a "household prescription book."

Seldom is warning more needed than that given on

page 103: "The fallacy of supposing that the glasses that are most pleasant for three minutes are necessarily the best to use for years is not so general now as formerly. Experience has taught the public much in this respect; but there are still many people who would scorn to buy a ready-made suit of clothes, but who still do not hesitate, in the infinitely more important and delicate matter of selecting glasses, to make their purchases without a measurement."

We read on page 114, "Bright white paper, particularly if its surface is glazed, is dazzling and irritating." This point is not unimportant, and it is to be regretted that the publishers of the book have not heeded it; the type, however, is very good.

Proceedings of the Association of Medical Officers of American Institutions for Idiotic and Feeble-Minded Persons. Sessions: Syracuse, June 8-12, 1878; Lincoln, Ill., May 27-30, 1879. Philadelphia: J. B. Lippincott & Co. 1879.

This report is well worth the perusal of any one interested in the study of mental disease and deficiencies. It contains several papers read at the last two meetings of the association. These papers are of varying degrees of scientific value, but all show an earnest effort on the part of the members to advance their specialty to its rightful position among the sciences. The effort should be commended, for the same causes conspire to prevent good literary and scientific work from them which prevent the superintendents of a majority of our lunatic hospitals from adding anything valuable to current medical literature. They are simply overworked and crushed by the necessity of attention to details of management. Legislatures and trustees demand, first of all, that superintendents shall devote their time to the economical administration of their institutions, while science must look out for herself. Nevertheless, the article, *par excellence*, of this report is by Dr. H. B. Wilbur, of Syracuse, superintendent of the New York State Asylum, one of the largest in the country, one of the most economically managed, and one wherein the friction of the machine is reduced to a minimum by a superintendent whose presence is felt in every corner of the institution.

This paper is upon the relation of speech, or language, to idiocy, and is a statement of the author's inferences from his observations and from an experience equalled only by his discretion in the selection of illustrative cases. He admits, at the outset, that articulate speech, or fluency of speech, is not the test of human intelligence, yet confesses, later on, that we are obliged to use it, for want of a better test, in estimating the degree of idiocy. He omits all theorizing as to conditions or lesions possibly causing the defective speech of idiots, and makes no mention of the lesions and many curious symptoms constituting the disease called aphasia, and which point so strongly to a definite location of the faculty of speech. He presents his paper merely as a contribution to the study of the interesting phenomena of speech. He disarms all criticism of his classification of idiots by saying that the special mode (of classification) adopted in any case is to be tested by the purpose it is meant to subserve. We wish some general classification might be adopted which would serve its purpose as admirably as Dr. Wilbur's classification serves his special object. Such papers as this can but prove a great incentive to other members of the association to

take time from their routine duties for the preparation of papers worthy of publication.

An interesting part of the report is an appended statement of the condition of the various American institutions, their development and progress.

We notice that Dr. George Brown, of Barre, while distinctly disclaiming ability to speak for the Massachusetts school, devotes rather more space to it than to the institution over which he presides, and takes his own *peculiar* method of complimenting the present management of the school, and the marked improvements brought about during the two years of most successful administration by Dr. Tuck. To any of his hearers or readers who were acquainted with the school, his disclaimer would seem at least superfluous.

Manual of the Dissection of the Human Body. Edited by LUTHER HOLDEN and JOHN LANGTON. Fourth Edition. Philadelphia: Lindsay and Blakiston. 1879.

Mr. Holden is the happy possessor of the faculty of writing interesting works on anatomy. A part of the charm consists in the frequent references to practical points, and in the explanation of the advantages and objects of details of structure. The fact that this is the fourth edition of the work before us attests its popularity. Manuals of dissection are of two kinds: one contains merely a short account of facts, — statements of the origin and insertion of muscles, of the chief relations of vessels and nerves. The student relies on his larger work for details, the manual being merely a guide-book for reference at the dissecting table. The other kind somewhat resembles a treatise on topographical anatomy, arranged, however, to assist the dissector rather than the general student. We do not propose to discuss which of these plans is the better; suffice it to say that this work is an admirable example of the second class. It is clear, interesting, and, in the main, correct, though we think we could point out some inaccuracies. We are particularly pleased with the diagrams of arterial anastomoses. It annoys us to notice the common error of describing the lateral sinuses as formed by the bifurcation of the longitudinal sinus. We imagine it would give Mr. Holden much trouble to find a head in which the arrangement corresponds with that in his diagram. We are very tired, also, of the stereotyped error, perpetuated in the wood-cut, of a section of the female pelvic organs. The author gives the old account of the course of the fibres in the optic chiasma without mention of newer views. Other criticisms might doubtless be made, but the book, as a whole, is a good one. T. D.

Clinical Lectures on Diseases of the Urinary Organs. Delivered at University College Hospital. By Sir HENRY THOMPSON. Fifth Edition. London: J. & A. Churchill. 1879.

The fifth edition of this valuable work will be read with unusual interest, now that so much attention has been attracted to this specialty by recent innovations. These have, however, received but slight attention, owing, probably, to the time of preparation of the work, an omission which will doubtless be corrected in the next edition. Sir Henry has also failed to keep pace with American views on the treatment of stricture. Notwithstanding this tinge of conservatism, these lect-

ures cannot fail to prove a source of pleasure as well as instruction to our readers, for they represent the matured views of a great teacher, and are prepared by a master's hand.

A Manual of Examination of the Eyes. A Course of Lectures delivered at the École Pratique. By DR. E. LANDOLT. Translated by SWAN M. BURNETT, M. D. Revised and enlarged by the author. Philadelphia: D. G. Brinton. 1879. 8vo, pp. 307.

The book presents a careful, accurate, and well-written account of the methods of examination of the eyes. Without superficiality, the subject is treated in a manner to meet the practical needs of the physician, while the reader who desires to master the more strictly scientific problems involved is referred to other sources of information.

The material is divided as follows: the objective general inspection of the eye; examination of the lids, conjunctiva, lachrymal passages, and all other portions of the organ accessible to the naked eye; determination of the distance between the two eyes, their height and protrusion; the movements of the eyes, particularly in their relation to strabismus; intra-ocular tension; acuteness of vision; refraction and accommodation; perception of colors; limits of the visual field, and indirect vision; ophthalmoscopy, including examination of the dioptric media by means of the oblique light.

While we heartily commend the book, one or two errors may be noticed. Donders is given (page 131) as authority for the statement that "for the higher degrees of hypermetropia strabismus becomes the rule." The original reads "*presque la règle*." Even this is not correct, nor does Donders assert it. What he does say is, "Strabismus is met with chiefly in mean degrees of hypermetropia." "In the highest degrees of hypermetropia strabismus is rarely observed."

Again, when examples are given to illustrate the selection of glasses in presbyopia (page 143), a glass is advised which will just bring the patient's near point to the distance at which his work must be kept. But this would not enable continued work with comfort; the near point should be brought somewhat within the distance for habitual work.

Such faults are, however, very few. The translator has accomplished his part of the work well.

Nature Series. Seeing and Thinking. By the late WILLIAM LANGDON CLIFFORD, F. R. S., etc. London: Macmillan & Co. 1879.

Of the four lectures which make up this little book, the first three contain a popular account of the various steps leading from the emission of light by a luminous body to the evolution of that complexity which we call thought. The method of presentation appears very well adapted to a general audience, and if the first two lectures are now and again marred by passages which, in one or two instances at least, are strangely tangled, this, to judge from a prefatory note, may be attributed to the fact that the lectures were printed from the notes of a short-hand reporter. It is somewhat odd that the third lecture, though dealing with that part of the subject not susceptible of so simple treatment, is yet free from the defects mentioned. The fourth lecture is an admirably simple and lucid exposition of the geometrical conceptions of a point, line, surface, and solid.

Eye-ball-Tension: Its Effects on the Sight and its Treatment. By W. SPENCER WATSON, F. R. C. S. Eng., etc., etc. London: H. K. Lewis. 1879. Pp. 70.

"Intending my little book to be mainly devoted to the treatment of eyeball-tension, I have only briefly alluded to the theories of its causation." Eyeball-tension the author proposes to substitute for the term glaucoma, "as being more expressive of the acknowledged condition of the eye in the disease in question." In a monograph on a subject so much studied and on which so much has been written as glaucoma one has a right to expect more than superficiality, but that is all that is to be found here. Though the book is "mainly devoted to the treatment," we quite agree with the author when he says, "The tables do not give any very clear evidence as to the efficacy of the different modes of treatment adopted."

Observations and Comments on Certain Convulsive Disorders. By HENRY DAY, M. D., F. R. C. P. London. Pp. 28.

This paper, read before the Medical Society of London, and selected by the council for publication in its transactions, presents, as the author justly claims, no facts nor explanations of especial value. The following observation alone, which occurred under his own eye, is worthy of special notice as illustrating an occasional cause of chorea. While riding along the road, Dr. Day saw a boy of his acquaintance in a dangerous position upon a neighboring tree. He called to him to come down, whereupon the boy, alarmed, let go his hold, and fell suddenly to the ground. On being picked up he gasped a few times, then began to scream as if in terror, and "then and there" the movements of universal chorea made their appearance, not passing away entirely for a month. J. J. P.

The Medical Register for New England. By FRANCIS H. BROWN, M. D. Boston: Houghton, Osgood & Co. The Riverside Press, Cambridge. 1880.

There are probably few who have not learnt the value of this little volume, which we cordially welcome for the coming year. Its contents and, where possible, its usefulness have again been largely added to. It has, in a comparatively few years, made itself a necessity for physicians, dentists, and pharmacists, at least in New England. The author and the publishers deserve credit for a result which could be reached only by much painstaking.

Consumption, and How to Prevent it. By THOMAS J. MAYS, M. D., etc. New York: G. P. Putnam's Sons. 1879. 12mo, pp. 89.

After calling attention to the fact that consumption is more destructive to human life than any other disease, and to the indifference and complacency with which we have come to view it, the author says, "that consumption is preventable is a reasonable as well as practical idea." He then gives brief hints to the laity on general physiological principles, on the general nature of consumption (which in one place he aptly describes as a low and miserable variety of inflammation), on the influence of food, air, soil, clothing, light, physical exercises, diseases, etc. The book is printed and bound in the Putnam's usual good style.

Medical and Surgical Journal.

THURSDAY, JANUARY 1, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Osgood and Company, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to
HOUGHTON, OSGOOD AND COMPANY, BOSTON, MASS.

INTRODUCTORY.

IN presenting the JOURNAL once more in a new form to our readers, we feel called upon to explain in a measure the various changes it was thought necessary to make during the past few years, — the process of evolution by which it has reached, we think we may venture to say, its present more or less perfected state. During the greater part of its existence the JOURNAL has preserved the form which we have just finally abandoned. A few years since, the double column was substituted, and was maintained through several volumes. When the present management assumed control it was thought that a monthly periodical might eventually prove better suited to the wants of New England, and a return to the old style of single column was decided upon to facilitate this change should it at any time be thought necessary. It was also supposed to be, among other advantages, a style better suited for the preparation of "reprints," a form of publication thought indispensable by authors who are wont to take pride in the production of their pens. Further experience has shown that, as the field of its labors has expanded and the limits of its old circulation have been outgrown, in order to keep pace with the leading periodicals of the day a form must be adopted which, although perhaps not the most ornamental, is certainly the most useful, and also undeniably, at the present time, the most popular. The modern "weekly" is able to present fresh from the author's pen material of all kinds, from the ponderous "quarterly" article to the latest item of professional news. There is a compactness which invites the attention of the reader.

The day of quarterlies and monthlies seems to be passing away, the demand of the present time being for small quantities at frequent intervals. We trust also that the modern spirit of enterprise will favor the patronage of a few active journals of this description, which will thus bring together on common ground the vast resources which the profession of this country is able to supply. As our announcement has shown, the editorial staff has been materially strengthened. We may mention more particularly in this connection the contributions of Dr. George B. Shattuck during the past year, who will have special charge of this department, and will be assisted by the other members of the staff. With the return of financial prosperity throughout the land we look forward with confidence to a more active support from the profession, which, like all other classes of the community, has felt the depressing influence of the "hard times,"

now happily a thing of the past. We feel justified, therefore, in expressing the hope that a prosperous and happy new year is in store for us all.

THE BELLEVUE TRAINING SCHOOL FOR NURSES.

THE annual meeting of this excellent institution was held on the 11th of December at the Nurses' Home, adjoining Bellevue Hospital, New York. Mr. William E. Dodge, Jr., presided, and a considerable portion of the visiting and house staff of the hospital were present in the large audience. Mr. Dodge read the annual report, in which it was stated that the hope entertained at the commencement of the work in December, 1872, that the school might become a college for the training of nurses and one of the recognized institutions of the country, had been realized. The pupils on entering were required to pass a preliminary examination in reading, writing, arithmetic, and English dictation. At the end of the first year they passed a second examination on the practical and theoretical duties of a nurse, and at the completion of the two years' course a final examination, of similar character, before a board composed of distinguished physicians and surgeons. Since the regular establishment of the school in May, 1873, ninety nurses have been graduated from it. Of this number two are in responsible positions as heads of training schools or matrons of hospitals, two are nurses among the poor, two have entered sisterhoods, and fifty-nine are still professional nurses. From this record, the report continues, it will be seen that the school has given an honorable, self-supporting occupation to a class of women whose intelligence and disposition have proved them to be fitted for it, while the continued and increasing demand for their services in hospitals and private families speaks favorably for the quality of the service they render.

All the female wards of Bellevue Hospital, two male wards, the Sturgis Pavilion, and the lying-in department are now nursed by the pupils of the school. In the Lying-In Hospital there have been one hundred and thirty-three births, and only one death from puerperal fever has occurred during the year. In the words of one of the visiting physicians, "The patients confined within its walls have enjoyed as great an immunity from infectious puerperal diseases as in the best private practice. The accomplishment of such results has been rendered possible only by the faithful, conscientious, and intelligent care rendered by your nurses, to whom I am glad to present my grateful thanks." The building appropriated to this hospital, having originally been an engine-house, was in many respects unsuitable for its present uses, but in consequence of the liberality of Mrs. Wm. H. Osborn such additions and alterations were made that it is now as comfortable and convenient as could be desired. To the same benevolent source Bellevue owes the erection of the Sturgis Pavilion, for the treatment of acute surgical cases. A record is kept by the superintendent of the conduct and efficiency of

each nurse during her two years' training, and after she leaves the school, if she wishes to continue her connection with the society, and obtain employment through its means, she is required to report at stated periods, in order that her diploma may be renewed.

In the original plan of the school was included the work of nursing among the poor, and it has never been lost sight of, though the managers have not yet been able to carry it to the extent that they desire. They report, however, that the work has been successfully begun by the female branch of the New York City Mission, and by the Society of Ethical Culture, presided over by the Rev. Dr. Felix Adler. There is appended to their report a letter from Dr. Adler on the beneficial results of trained nursing among the poor, and this contains the following extract from the report of one of the district physicians of the Demilt Dispensary in regard to the services of the nurse working under his direction: "She has a quick perception of what is needed, and she readily and cheerfully does it, no matter how repulsive the task may be. She visits patients intrusted to her care at unexpected times, that she may see them as they are from the beginning to the end of their illness. One must take time to win the confidence of these people, and find out the secrets of their poverty and distress, and so know how not only to alleviate but often to prevent misery. This work the nurse is doing steadily and faithfully, and the information she brings me is invaluable. The only wonder to me now is how I got on with these cases without a woman's help. She visits from morning to night, seeing that my medicines are given as directed, inaugurating and enforcing much-needed sanitary measures, often making with her own hands articles of clothing for the sick, while she distributes with judgment the articles so generously supplied by your society. Surely the blessings of many ready to perish will be hers, for not one of them speaks of her but with the kindest expressions of gratitude and regard."

The good health that the pupils of the school have enjoyed proves that their occupation, when properly conducted, is not injurious. Only two deaths have taken place in seven years, and during the past summer there was not a case of illness in the school. Care is taken that the nurses shall not be overworked, and that the diet shall be generous and good, while the bright and comfortable home in which they live when not engaged in the hospital no doubt contributes largely to the maintenance of their health.

In concluding their report the managers offer their thanks to the head nurses and to the graduates: to the former for their loyal devotion to their work, not only in instructing their pupils, but in the example they set of a faithful and tender performance of painful and at times repugnant duties; and to the latter for the good work that they have done wherever their lot has been cast, among the rich or poor, in hospitals or asylums, thus reflecting credit upon the school, to which they always gratefully acknowledge their obligations.

On this occasion diplomas were awarded to twenty-

three graduates, twelve of whom were from New York, two from New Jersey, one from Massachusetts, one from Maryland, one from North Carolina, one from Tennessee, one from Ohio, one from Michigan, one from Connecticut, one from Canada, and one from Holland. Each graduate was also presented with a pocket-case of instruments. The annual address was delivered by Dr. William M. Polk, professor of obstetrics in the University Medical College, and in the course of it he contrasted the present condition of hospital nursing and the advantages for obtaining good nurses with the state of affairs that existed when he entered the medical profession, only a few years ago.

It is expected that during the next year there will be one hundred and fifty pupils in the school, applications for admission having been received from all parts of the country.

MEDICAL NOTES.

— In an obituary notice of the death of Soelberg Wells, M. D., F. R. C. S. Eng., the *London Lancet* says: "Scarcely a month has passed but we have been called upon to announce and to make publicly known the loss of a distinguished front-rank man in our profession. The mortality has been especially great among metropolitan practitioners. The removal of such men as Murchison, Tilbury Fox, Maunder, Black, Leared, Callender, and Harry Leach must for a time, at least, materially weaken us. And now we have to add to this black list the name of Soelberg Wells, the eminent and skillful ophthalmologist, who died on the 2d inst. at Cannes, whither he had resorted for the winter in quest of health, and where he was buried on Friday last.

"The story of Wells's illness and failing health is a sad one. Tall, handsome, and of splendid physique, he enjoyed excellent health and spirits until about four years ago, when he somewhat suddenly broke down, and was compelled to leave his work to spend some months in the south of France and in Italy. From that time, with a few deceptive intermissions of apparent health, it was painfully evident to all his friends that he was smitten with a mortal malady, though he himself, up to within a very short time of his decease, cherished the hope that his symptoms were chiefly functional, and that rest and a genial climate would restore him to health and strength, and enable him to return to the work on which so much of his best time and energies had been spent. During the past summer he resided with benefit at Aix-la-Chapelle, and returned to London in October. He attempted to resume his public and private duties, but only to relinquish them at once. The severe weather at the end of October proved seriously prejudicial to him, and he was ordered by his medical advisers to start without delay for Cannes. This he did about the beginning of November. The weather, however, seems to have been as unpropitious at Cannes as in London, and within a week of his death he stated in a letter to the writer of this notice, 'My progress to

convalescence has been greatly retarded by the bad weather here, which, instead of being beautifully warm and sunny, is rainy, cold, and very tempestuous, owing to a very severe mistral which has been blowing for the last ten or twelve days, confining me to the house.' A week later he succumbed to an obscure disease of the liver.

"It is not easy to assign to Wells his proper place as an ophthalmologist. German blood ran in his veins, and much of his education and training, both general and professional, was conducted under the guidance of German teachers. His early professional education was begun at Norwich, and finished at Edinburgh, where he graduated in 1856. Though possessed from the first of ample and even independent means, he preferred to follow an active career, and was induced to devote time to the study and practice of diseases of the eye. In furtherance of this pursuit he went to Berlin to work in the famous clinic of the late Professor von Graefe, to whom he soon became a valued assistant, and with whom he formed a firm and life-long friendship. Under the superintendence and supervision of Von Graefe, Wells was carefully trained in every department of the science and art of ophthalmology. Indeed, his special training was, perhaps, unique in its range and completeness.

"In 1860, when Wells returned to England, he was appointed clinical assistant to Mr. Bowman at the Royal London Ophthalmic Hospital, Moorfields, which post he held until his appointment as assistant surgeon in 1867. In 1873 he was promoted to the rank of surgeon, which office he continued to hold at the time of his death. Besides this he was professor of ophthalmology in King's College, and ophthalmic surgeon to King's College Hospital. None of these advantages and opportunities were lost on Wells. In spite of the temptation to ease and dilettanteism to which a large fortune exposed him, Wells, as long as his health allowed him, discharged his duties punctually, and was zealous alike as a worker and teacher. He was a first-class specialist of the best type. His special acquirements were laid on a good foundation of general medical knowledge. One of his chief merits was that, by his writings and teaching, he familiarized English students and practitioners with the best clinical and scientific investigations of the eminent ophthalmologists of Berlin, Vienna, and Utrecht. His treatise on Diseases of the Eye, and his book on Long, Short, and Weak Sight, the former of which has reached a third and the latter a fourth edition, are the best works in our language on the subjects of which they treat. Their appearance inaugurated a new era in English ophthalmological literature, and they will long retain their place among the surest and safest guides. As a practitioner Wells was shrewd and sagacious, cautious in difficulties, and possessed a strong faith in local remedies. He was trusted and respected alike by patients and practitioners, and before his health failed he possessed a rich and select *clientèle*. Wells leaves no near relative, but his loss is keenly felt and deplored by a large number of friends and colleagues."

— We have several times alluded to the necessity of making the city registrar's department subordinate to the Board of Health. Last year a petition asking for such a change was sent to the city council of Boston, signed by over three hundred physicians, including all the leading members of the profession. Owing, however, to the pressure brought to bear by the friends of the registrar's department, the movement failed. This year an appeal is to be made direct to the legislature, asking for such legislation as shall place the duty of registering all returns of deaths and of granting burial permits in the hands of the Board of Health in all cities and towns having such a board. By the census of 1870 the number of cities in this country of over fifty thousand inhabitants was twenty-four, and in all of these, with the single exception of Boston, the local boards of health have entire charge of the registration of births and deaths. It is high time that such a change was made in Boston, and we hope the profession will aid the movement, so far as their influence as petitioners will go.

— The inhabitants of the Connecticut, Ammonoosuc, and Passumpsic valleys, from Massachusetts to Canada, have been unusually free from typhoid fever, diarrhoea, and dysentery during the year 1879. Diphtheria has prevailed fatally in many localities. Piermont, Haverhill, Lisbon, and Franconia in New Hampshire, Barnet, Newark, and some other towns in Vermont, have each had more or less fatal cases.

— A human skeleton was recently discovered beneath a barn near Woodsville, N. H., over which was written for the daily papers a very pathetic story of beauty, love, parental objection, seduction, abortion, and death. The fact is that there was nothing to indicate positively the sex, the pelvic bones being much decayed; the wisdom teeth were fully grown; the molars were much worn; all the long bones were fully developed. There was one condition of interest to physicians: the first and second lumbar vertebrae were firmly ankylosed. Everything would indicate that this beautiful "maiden" may have been about forty years of age, and *may* have been a man.

— The *Medical Press and Circular* calls attention to a case of anuria, reported in the *Union médicale*, November 4th, in which the patient lived for seventeen days without passing a drop of urine. Death occurred on the seventeenth day. There was no autopsy.

— The same journal mentions the fact that the classical work on Diseases of the Chest, by the late Dr. William Stokes, of Dublin, is to be reprinted by the New Sydenham Society.

PHILADELPHIA.

— At the last meeting of the Biological and Microscopical Section of the Academy of Natural Sciences, Prof. J. Gibbons Hunt expressed dissatisfaction with the results obtained by the present methods of making and mounting preparations, and stated that the character of the work exhibited at the meetings had not been up to what the critical student would desire. No matter how carefully preparations are made, they

lose much of their true character by the methods in general use among microscopists. He condemned Canada balsam, and said that he had never seen even as common a thing as a human hair mounted in balsam which would enable the observer to study the details of its structure. Alcohol for hardening specimens, previous to making sections, he declared to be even more objectionable, on account of the considerable changes produced in the structures to be examined, giving students very often erroneous views. He preferred solutions of chromic acid for hardening specimens, and recommended watery fluids for mounting, of which glycerine should form the basis. In this way sections of soft tissues are made with the least change, and may be readily preserved.

Dr. Carl Seiler, in commenting upon the above communication, said that he thought that Dr. Hunt had overrated the objections to Canada balsam, as in his own opinion in many cases it answered sufficiently well. He also commended the use of carmine for fine injections, in opposition to the lecturer, and said that these injections are not made for the purpose of showing the structure of the walls of the capillaries, but in order to demonstrate their relations to surrounding structures.

At the same meeting, Mr. J. A. Ryder stated that a small fish had recently been brought to him from New Jersey, which had very large white cysts or sacs imbedded beneath its skin in the muscles. These cysts were much of the shape and size of a grain of wheat, about twenty in number, in a fish one and a half inches long. The contents of these sacs was a thick, whitish material of the consistence of cream. This material, when brought under a power of nine hundred diameters, was found to be composed of a vast number of very minute oval bodies with a long tail. There were, without exaggeration, not far from half a million of these bodies in this one little fish. They are to be found as parasites in almost all classes of animals, even in man, and are known under the name of *psorosperms*. They are supposed to be entirely harmless when taken as food; indeed, Dr. Cobbold, a great authority on parasites, says that in eating of the heart of a bullock infested with them he must have taken in at least eighteen thousand of them. The case described is of interest, because they have not, as far as known to Mr. Ryder, been recorded as being found in this rather rare and curious little pike-perch (*Aphododerus*), a fish quite peculiar to the United States.

—A series of clinical conferences by the students of the graduating class (somewhat on the Harvard plan) has been inaugurated this winter, by Professor DaCosta, at the Jefferson Medical College, and has been entered into with considerable zest by those interested; they will undoubtedly prove very popular and valuable. Professor Gross continues his genial conversational method of quizzing the students, frequently calling upon the class for a diagnosis or for obvious suggestions as to treatment. At his clinic the operation of lateral lithotomy has been performed eight times this session, with one death.

ST. LOUIS.

—The monthly meeting of the St. Louis Obstetric and Gynecological Society was held on the 18th of December. The evening was devoted to the discussion of Dr. Maugh's paper on Puerperal Fever, a synopsis of which has been published in the JOURNAL. Drs. Cole, Barret, Prewitt, Engelmann, Ford, Moses, and others took part in the discussion. The points considered were, first, May puerperal fever be produced by mental causes acting upon a constitution in a puerperal condition, or is it always a septicæmia or pyæmia? Most of the members thought that mental conditions were capable of causing puerperal fever. Some, however, represented by Dr. Prewitt, took the view that it was always due to the absorption of septic material. Another cause, not given in our synopsis, was spoken of, namely, hæmorrhage, which, by depriving the blood of its red corpuscles, destroys its power of oxidizing the septic material taken into the system from the lacerated uterine surface.

The next point considered was the relation of puerperal fever to small-pox, scarlatina, and erysipelas. The society seemed to agree upon the practical point that when a physician was treating one of these diseases he should avoid puerperal cases, though they did not think small-pox or scarlatina was likely to produce child-bed fever, and many thought this impossible. In proof of this, Dr. George Engelmann cited two cases. In one, during pregnancy, the mother had small-pox, and at seven months miscarried; the foetus was dead and pock-marked; the mother's recovery was slow, but there was no evidence of puerperal fever. In the other, a domestic, who was pregnant, nursed some children, ill with scarlet fever. She took the disease, and, while the rash was at its height, was taken in labor and was delivered. The scarlatina ran its usual course, but there was no appearance of puerperal fever.

With regard to erysipelas, on the other hand, Dr. Barret cited two cases of puerperal fever in his practice which appeared traceable directly to it. Dr. Maugh's stated that he had also seen many cases in which the two diseases seemed related as cause and effect, where, the mother dying of puerperal fever, the child died of erysipelas, and a pregnant woman who nursed the child died of puerperal fever, and her child again in turn died of erysipelas. Some of the society thought that the cause was the decomposing tissues produced by the disease, and not the erysipelas poison. In respect to the treatment, but little faith was placed in veratrum viride and opium; but the very free administration of quinine, muriated tincture of iron, and whisky was regarded as the most promising course to pursue.

—On the 11th of October, two very interesting monsters were exhibited to the St. Louis Medical Society by Dr. Maugh's. One was given to him by Dr. Schmidt, of Cairo, Ill. It was supposed to be an eight months' foetus. At its birth it was so hideous that it frightened the mother terribly; it howled fearfully, and she imagined that it barked like a dog. The eyes were imperfect, the ears scarcely raised above the

surface of the head, the fingers contracted, the mouth large, wide, and gaping, and the skin was striped like that of a zebra. The doctor attributed this appearance to an intra-uterine disease of the epidermis, which resulted in the laceration of the skin, the fissures sometimes extending through the skin, and even into the muscles. With the exception of these peculiarities the child was well formed. Six or eight similar cases were reported up to 1843. These freaks of nature are popularly attributed to mental conditions. In this case, in the second month of pregnancy the mother accidentally stepped on a dog in the dark, and was very much frightened; this accounted to her for the peculiarities of her child. The doctor also spoke of a case in his own practice, where a pregnant woman dreamed that she gave birth to a hermaphrodite, and afterwards talked about the dream considerably. When the child was born, strange to say, it was as near a hermaphrodite as humanity ever comes. Fortunately it died at the age of three years.

The second monster was still more interesting; the head and arms had been amputated in utero; the left arm at the junction of the middle and lower third of the humerus, and from this stump there had grown a perfect and most beautiful hand, there being four fingers and a thumb with their nails. This amputation and attempt at reproduction must have occurred when the embryo was low down in the scale of organization, on a par with the salamander. The monster was born at full term, and a twin. The other child was perfect and healthy.

Correspondence.

LETTER FROM PORTLAND.

THOUGH nothing particularly startling has occurred in medical circles in Maine during the year now so near its end, there have been a number of events of sufficient interest to the profession of the State to seem to be worthy of a record in the JOURNAL.

The annual meeting of the Maine Medical Association, held in this city in June, was one of the most successful in the history of the society, as regards not only the numbers in attendance, but also the character of the discussions, and the harmony of feeling which prevailed. In the last-named respect, it afforded a marked and grateful contrast to the session of last year, which will long be remembered for its stormy debate concerning the punishment of a member who had been tried by the censors and found guilty of conduct unworthy and unbecoming a gentleman and member of the association. It is very probable that the tranquillity of this year's meeting was largely due to the fact that the constitutional right of the society to regulate its own membership was definitely settled by the protracted and exciting discussion in 1878 on the question of expulsion. Everybody seemed to feel that there would be no further necessity of devoting time to that subject, and, as no other portion of the organic law or the regulations demanded interpretation, the whole of the time of the association could be freely devoted to its legitimate objects.

The president, Dr. M. C. Wedgwood, of Lewiston, made a number of valuable recommendations in his in-

augural; but that which attracted most attention was the suggestion that the association have an annual dinner. Until quite recently it has been usual for physicians in this city to entertain the visiting doctors with a collation on the evening of the second day of the session; but the enjoyment which was experienced at these offerings of toothsome edibles was not so intense as to make it an object to continue them, and for several years no portion of the session has been even ostensibly devoted to social intercourse. The proposition of the president gave voice to an almost universal feeling in the society, and the only difference of opinion arose with regard to the best way of executing the design. All favored a good dinner; but, while some wanted it paid for from the funds of the association, others thought it would be wiser for each person attending to purchase his own ticket. The latter method was finally adopted, and a committee was appointed to take charge of the entertainment.

A good number of well-written papers were presented, the topics treated embracing all departments of medicine. The essay which called forth the longest and most animated discussion was on The Use of the Obstetric Forceps, by Dr. H. N. Snell, of Portland, an entire evening being consumed in the debate. With few exceptions, the speakers agreed as to the desirability of employing these instruments much more frequently and at an earlier point in labor than the older authorities advise or sanction.

The annual oration was pronounced by Dr. C. A. Packard, of Bath, who discoursed most interestingly on The Physician an Educator, taking the ground that there is great need among the people of instruction on matters which physicians alone can properly impart, and that it is the duty of the profession to make its influence emphatically felt in educational matters. In this way only can the community be protected from the baneful impositions of quackery, which in numberless forms trifies with the lives of the people, and from the insidious influences which at present are to be found in almost every household.

In the line of business, quite a number of applicants were admitted to membership, and a few were rejected; the third Tuesday in June was selected as the time for holding the next meeting; and steps were taken with reference to the publication of the records of the first ten years of the association's existence. It is to be regretted that action was not taken concerning the adoption of the metric system. The failure to do so was an oversight on the part of a committee, and at the next meeting the association will probably array itself on the side of progress in this matter, as it already has in most others. The opportunity of calling attention to the convenience of the metric system in writing prescriptions was not altogether lost, however; and every member was supplied with tracts on the subject, which cannot fail to make some impression upon even the severest conservative.

The principal officers for 1880 are Dr. S. C. Gordon, president; Dr. C. O. Hunt, secretary; Dr. A. S. Thayer, treasurer; and Dr. G. F. French, chairman of the censors.

The Maine General Hospital is enjoying unexampled prosperity. In spite of the malicious attempts to defeat an appropriation from the state treasury, the legislature voted five thousand dollars, as usual; and in January a subscription was started to extinguish the debt which for years had been impeding the

progress of the institution. In a short time, the whole amount needed, nearly twelve thousand dollars, was raised in Portland, thus affording new evidence of the high esteem in which the hospital is held by those who have the best opportunity to observe its management and its work. The invested fund is as yet small, as is generally the case with young institutions; but it is increasing every year, and it is hoped that before long it will be sufficient to enable the hospital to dispense with legislative gifts. The proportion of surgical patients is naturally very large, and most of them require operative treatment. Recently the antiseptic method has had an extensive trial, and the results have been very gratifying.

Affairs at the Maine Insane Hospital, at Augusta, have been somewhat unsettled all this year. In the general official proscription which followed the inauguration of the present governor, the trustees of the asylum were included, with the single exception of the venerable Dr. John T. Gilman, who remains on the board as an example of executive clemency. It is deplorable that such offices should not be kept free from all taint of partisan politics. No change in the superintendency has as yet been effected, though efforts in that direction have been made, it being commonly understood that Governor Garcelon has requested the resignation of Dr. Harlow, who for many years has been at the head of the institution.

While so many of the States are establishing Boards of Health, Maine stills lags behind, and, if one might judge from the amount of apparent interest in the subject, is no nearer the adoption of sanitary measures than it was a decade ago. Year after year a committee of our association goes before the legislature, and presents the case in all its bearings. But, while our law-makers, as individuals, very generally admit the force of the arguments in favor of the board, when the question is put to vote, there is always an overwhelming majority against it. It is said, in opposition, that there is no such amount of preventable disease as the medical men allege; that the doctors only want to get their hands into the money-chest of the State; that the movement is solely in the interest of the cities, especially Portland, and so forth and so forth,—all the hostility which frames itself in open speech being equally creditable to the intelligence of the legislature. One bucolic orator assumed an attitude of charitable regard for our profession, and objected to measures which would diminish the amount of sickness, because, as he said, not half the doctors are able to get a living now. All such talk appreciably influences the men who are usually sent to our capital to construct laws, and so we are still without a board of health. But we are not entirely discouraged, and next year intend to try again, though with no very flattering prospect of immediate success.

Health matters have had a good deal of attention in Portland since last spring. The subject has been forced upon the attention of our citizens by the condition of the cove which lies on the northern side of the town, and receives the sewage from fully half of our area. On hot nights the stench from this region was often appalling, frequently awakening people from sound sleep, obliging them to close their windows, and apparently causing much illness, as well as discomfort. The complaints were so numerous and from so respectable a class as to demand some attention, and in August the mayor appointed Dr. F. H. Gerrish and Dr.

C. A. Ring a commission to investigate the causes of the nuisance, and report measures for its suppression. After several weeks of work, the commissioners reported at great length to the effect that they found many causes which combined to produce the mephitic odors in question, of which the most prominent were the discharge of sewage in places whence it could not be removed by the action of the tide; the bad condition of the sewers, and especially of their culverts; the very common employment of accumulative privies, many of which were found to be in a condition of almost incomprehensible filthiness; and the method of emptying privies, which is by bailing. They recommended the construction of an intercepting sewer on the northern shore of the city, by means of which the sewage might be conducted into deep water and swept out to sea by the tide; the drainage of certain morasses into which unauthorized sewers have been emptied; the systematic and frequent cleansing and flushing of the culverts; the ventilation of the sewers; and the utter abolition of the system of accumulative privies. This report was published in both the morning papers, and received the approval of the physicians of the city, as well as that of the citizens in general; but nearly three months have now elapsed since it was made, and the city government has not taken the smallest official notice of the subject. The people are not much annoyed with foul odors in the cold seasons, and seem to have forgotten what sufferings they endured last summer; but when spring opens, we shall have the old smells back again in full force, and half the adult population will be cursing the inefficiency of the city council. It has been suggested that our only way out of the difficulty is to elect our municipal officers on a strictly sanitary platform, pledged to reform these hygienic abuses. This plan might work very well, if the election came in June or July; but as it occurs in the early part of March, when we have been for six months without such trouble from our unhealthful conditions as the non-medical mind can easily see is productive of disease, it is highly improbable that such a movement would meet with any considerable encouragement. A frightfully devastating epidemic of diphtheria or typhoid fever might possibly startle our people into a recognition of the necessity of doing something; they are apparently waiting for some such stimulus to mental activity in this direction.

The class in the Medical School of Maine was large this year, in spite of the entrance examination. The institution is keeping up its reputation for severity at the final examination, over sixteen per cent. of the applicants for a degree being rejected. The vacancy in the chair of pathology and practice, occasioned by the resignation of Professor Palmer, has been filled by the election of Dr. Israel T. Dana, of this city, who, after the interval of a decade, returns to the position which he filled for a long series of years so acceptably to the school and the profession. GAMMA.

PORTLAND, December 12, 1879.

GRITT'S SUPRA-CONDYLOID AMPUTATION OF THE THIGH.

MR. EDITOR, — Under the above heading, in a late number of the JOURNAL, I find a communication from William Child, M. D., defending the claims of the late Dr. Van der Kieft as the first to propose and execute

the new method of management of the patella in amputations at the knee-joint. In this connection, I wish to place on record two cases. On the 13th of August, 1872, I was called to see Harvey Pierce, who had just sustained a compound fracture implicating the knee-joint, caused by the kick of a horse. The case being one that demanded amputation, I proceeded, with the assistance of Dr. Wilson, of Lockport, New York, to operate in the usual way. In making my flaps, I cut the posterior one too short, so much so that if I had removed the patella I should have lacked sufficient tissue in my anterior flap to bring it into proper apposition with the posterior. In this extremity I decided to excise the condyles of the femur. This having been done, my flaps came nicely together, bringing the patella over the end of the femur. The patient made a speedy recovery, riding out to church four weeks from day of operation. In a subsequent case of excision of the knee, followed by sloughing of the foot, rendering amputation necessary, I operated as in my first case, the condyle having been removed in the first operation by excision, with good result. The patient died a year after, and upon post mortem examination of the stump I found the patella firmly united to the end of the femur by bony deposit. The only difference between the operation performed by Dr. Van der Kieft and the one executed by myself is that I did not remove the inner structure of the patella. In the *Peninsular Journal of Medicine*, of Detroit, November, 1875, the reader will find a more detailed account of my cases.

J. H. EVANS, M. D.

ELK RAPIDS, MICH., December 9, 1879.

MASSACHUSETTS DENTAL SOCIETY.

THE following resolutions were adopted at the last meeting of the Massachusetts Dental Society:—

Whereas, serious charges against Dr. George F. Waters, a member of the Massachusetts Dental Society, in connection with the death of Mr. George A. Gardner, of Brooklyn, have been published in the papers of the country, *Resolved*, that from the published reports and our own investigation the Massachusetts Dental Society consider Dr. Waters entirely innocent of any unprofessional or injudicious conduct in this case, and that his treatment was wise, cautious, and safe. *Resolved*, that the charge that Dr. Waters used arsenic in this case is entirely and wholly false. In such a case no man possessing the rudiments of a dental education would use arsenic. *Resolved*, that the course of the *New York Times*, in first publishing this sensational report without taking proper means to investigate the charges, is an outrage upon truth and the rights of citizens, and that its subsequent conduct in not making correction and reparation, as far as possible, was not fair and honorable, and as this charge has seriously affected the business of Dr. Waters, by unjustly undermining the public confidence in him, we consider that that paper is peculiarly liable for damages. *Resolved*, that we know Dr. Waters to be one of the best informed and most intelligent investigators in the profession, and entirely worthy the fullest confidence of the community.

Unanimously passed December 12, 1879.

L. D. SHEPARD, president, DWIGHT M. CLAPP, secretary.

ERUPTION FOLLOWING THE USE OF SALICYLATE OF SODA.

MR. EDITOR,—I send you this note on the action of salicylate of soda. Mrs. W., aged forty, consulted me December 5th for pain and swelling of the left ankle-joint. Diagnosing acute rheumatism, I prescribed salicylate of soda in fifteen-grain doses every three hours. Two days after I was called to see her on account of an eruption; this was confined to the inner surface of the fore-arms and the outer surface of the thighs, and was a hybrid between lichen and eczema, or lichenoid eczema. She also complained that the medicine nauseated her, but her ankle was better. The medicine, therefore, was discontinued, and in a few days the rheumatism became worse, implicating both ankles. The medicine being resumed the eruption reappeared in full bloom with the same gastric phenomena as before.

Whether this is to be explained on the *post hoc*, *propter hoc* theory I am incompetent to determine. Has any one any light to shed on this question?

C. S.

NORTHAMPTON, December 15, 1879.

COUNTRY PRACTICE.

IN the practice of Dr. N. C. B. Haviland, Bath, N. H., R. S. had the right wrist severed by the "beater" of a threshing machine. All the metacarpal bones were carried away; the carpal bones were dislocated or fractured; the ends of the radius and ulna were crushed off; the back of the hand was wholly denuded of soft parts; the soft parts of the palm were uninjured; the fingers were untouched; the hand remained connected with the forearm only by the tendons, a few shreds of muscle, and a narrow isthmus of skin. Amputation was performed by Drs. Child and Haviland of Bath, and C. H. Boynton of Lisbon, N. H. Sulphate of ether and elastic bandage were used. The patient did well.

In the practice of Dr. William Child, S. C. was caught by a rapidly revolving shaft; right arm wholly torn away from near the shoulder-joint; right thigh fractured at the middle; left leg and foot bones were crushed nearly to the knee, though the skin was not broken, the patient having on rubber boots. Amputation of arm was performed by Drs. Child and Boynton. Sulphur of ether and chloroform employed. Legs not amputated. Patient died of nervous shock in about thirty-six hours.

In the practice of Dr. Gibson, Woodsville, N. H., S. C. had the right foot crushed by the wheel of a locomotive. Chopart's amputation was performed by Drs. Gibson and Child. Sulphate of ether and elastic bandage used. Recovery rapid and good.

INFANTILE CONVULSIONS.

MR. EDITOR.—Five weeks ago I was present at the birth of a robust and healthy child. When twenty-one days old, while in apparent health, it was seized with convulsions. A teaspoonful of castor-oil had been given it by the mother the night previous, and I learned that it had been fed by hand very irregularly; also that anise and catnip had occasionally been given,

the latter the day before. The spasms were clonic on the left side and tonic on the right; face congested and convulsed towards the left; muscles of respiration acting synchronously with those of the left side; arms more convulsed than legs; pupils widely dilated, eyes injected; thumbs in palms. The attack lasted five minutes, and as it ceased the child screamed violently, and drew up its legs, while the abdominal muscles were quite firmly contracted. Twenty drops of paregoric were given, stupes were applied to the abdomen, the lower part of the body was immersed in mustard water, cool lotions were applied to the head, and a soap suppository was inserted, which soon came away in a mass of green and white curds. In five minutes, and after a scream or two, convulsions of like character recurred, followed by screaming. Thirty drops of paregoric were now given, and another suppository. A spasm followed in the usual time; face purple, pupils dilated to the utmost, and while terribly convulsed the child screamed most piteously, when the noise of a stool was heard, and very soon it became quiet, and seemed to sleep; breathing, pulse, and muscles natural. The respite was of short duration. Chloroform was now administered by inhalation, and during the succeeding forty-eight hours the babe was carefully kept under its influence, with intervals long enough to know that when it was suspended for five minutes the convulsions reappeared, but with less violence. On

the morning of the fourth day a perfectly healthy-looking stool appeared, the child for the first time began to take milk, and until date has been in a natural condition.

A. S. McCLEAN, M. D.

SPRINGFIELD, December, 1879.

ABSENCE OF AMNIOTIC FLUID.

MR. EDITOR.—I was called early in the morning of October 27, 1879, to see Mrs. B., primipara, aged nineteen years, whose health was good, and had been during the whole term of pregnancy; there was nothing peculiar in the case, except that lactation had begun in the third month, and to such an extent as to keep her clothing constantly wet. After a tedious labor of twelve hours she was delivered of a male child weighing ten pounds. It was "a dry labor,"—the liquor amnii was absent.

One year before the above case I attended Mrs. F., aged twenty-eight, and mother of two children. Labor lasted seven hours, and she gave birth to a female child,—eight pounds. This case, like the former, was without the amniotic fluid. I do not think that I could have been mistaken. In the first case I ruptured the membranes, and was alike attentive to both. Let us hear from the readers of the JOURNAL on this subject.

Two thousand one hundred and fourteen deaths were reported; 904 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 415, consumption 345, lung diseases 279, diphtheria and croup 206, scarlet fever 73, typhoid fever 33, diarrhoeal diseases 30, measles 21, whooping-cough 16, malarial fevers 12, erysipelas eight, cerebro-spinal meningitis six, small-pox four. (In addition, Chicago reports 41 deaths from diphtheria and croup, lung diseases 21, scarlet fever 11, consumption 10, typhoid fever and malarial fever three each, measles and erysipelas two each, — total deaths not given.) In the cities excluding Chicago, from *measles*, New York 20, New Haven one; from *whooping-cough*, Boston seven, Cincinnati two, Brooklyn, Baltimore, District of Columbia, Cleveland, Pittsburgh, New Haven, and Gloucester one; from *malarial fevers*,

New York four, Brooklyn and New Orleans two, St. Louis, Baltimore, Charleston, and Nashville one; from *erysipelas*, Brooklyn three, New York two, Fall River, Springfield, and Salem one; from *cerebro-spinal meningitis*, New York, Philadelphia four, St. Louis, and Haverhill two; from *small-pox*, Philadelphia four. Diphtheria continues far the most fatal of the "zymotic" diseases, and caused 20 more deaths than in the preceding week; whooping-cough and erysipelas were less fatal, lung diseases more so. In Massachusetts, the small-pox in Worcester and Fall River seems to be entirely under control; scarlet fever, diphtheria, and whooping-cough were increasing in fatality in 17 cities and towns reporting.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.		Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

¹ O, cloudy; C, clear; F, Fair; G, fog; H, hazy; S, snow; R, rain; T, threatening.

For the week ending November 29th, in 146 German cities and towns, with an estimated population of 7,592,985, the death-rate was 23.2 against 23.4 of the previous week. Three thousand three hundred and eighty-one deaths were reported; 1511 under five years of age; pulmonary consumption 466, acute diseases of the respiratory organs 374, diphtheria and croup 156, diarrhoeal diseases 143, scarlet fever 80, typhoid fever 67, measles 58, whooping-cough 46, puerperal fever 16, small-pox (Dantzic and Berlin) two. The death-rates ranged from 14.0 in Hanover to 36.0 in Dortmund; Dantzic 25.2; Breslau 23.1; Dresden 19.3; Berlin 22.1; Leipzig 23.2; Hamburg 25.7; Bremen 23.1; Cologne 23.8; Frankfurt 17.7; Strasburg 28.8. In the same week, Vienna 26.7; Prague 31.2; Paris 24.4. In the 20 prominent Swiss cities and towns, diarrhoea, scarlet fever, and diphtheria were most prevalent of the acute diseases, although diminishing. There were two deaths from small-pox in Geneva.

For the week ending December 6th, in the 20 English cities and

towns, with an estimated population of 7,383,999, the death-rate was 27.4 against 25.2 of the previous week. Three thousand eight hundred and eighty-three deaths were reported: diseases of the respiratory organs 612, scarlet fever 162, measles 150, whooping-cough 94, fever 54, diarrhoea 45, diphtheria 24, small-pox (London) five. Scarlet fever is epidemic in London, Liverpool, Manchester, and Sheffield; measles in London, Liverpool, and Leeds; small-pox is increasing again in London, and lung diseases are very wide-spread and fatal. The death-rates ranged from 18.2 in Salford to 43.8 in Wolverhampton; London 27.2; Brighton 29.6; Bristol 28.3; Birmingham 27.8; Liverpool 37.3; Manchester 28.0; Leeds 25.6; Sheffield 23.4. In Dublin (scarlet fever and small-pox the most fatal of infectious diseases) 37, Edinburgh 23, Glasgow 25. In the 20 Swiss cities and towns there is a considerable increase in diphtheria, other infectious diseases declining; no deaths from small pox, scarlet fever, or whooping-cough; lung diseases very prevalent and fatal. Geneva 19.4; Zurich 22.2; Basle 27.9; Lucerne 27; Vevey 11.5.

SANITARY ORGANIZATION OF NATIONS.¹

BY HENRY I. BOWDITCH, M. D.

SANITARY science, though of such recent growth, is now fast becoming a most important branch of preventive medicine. I have therefore thought that I could not choose a subject more important than sanitary organization in its widest sense. I give it as my quota of work towards inaugurating the new and excellent plans adopted by this society.

And let me here say that I not only do not shrink from, but I court, the severest criticism upon what I shall advance. I like nothing better than the honest and free expression of opinion. It proves that the matter has attracted some attention. So far, however, as animated discussion in Boston societies is a criterion, one would think that no topic is thought worthy of being discussed at all; for even those subjects universally admitted to be of the most interesting character are usually received with a dead, funereal silence on the part of a Boston medical audience.

Sanitary organization, in its widest sense, would begin with man as an individual and terminate in international law, or his relations with his fellows of the whole race. I intend to throw out a few hints only upon each one of these topics.

Perfect health should be a matter of profound interest to every human being. Without it few of the relations of this life can be fully sustained. It should therefore be constantly sought after by each man and woman; by the state for its citizens; by a nation for the states and communities of which it is composed; and, finally, by every sovereign power in its relations with any and all other civilized or uncivilized sovereignties. The fine Latin maxim "*Salus populi lex suprema*" is peculiarly appropriate in any discussion of these questions.

I propose to submit a few thoughts upon them, beginning with the international relations, and concluding with man as an individual member of the community, but upon the basis of whose perfect health the idea of all sanitary legislation is primarily founded.

INTERNATIONAL SANITARY LAW.

Although upon the question of quarantine every nation has felt that it had the right summarily to deal by law, or by force if need be, with any other nation, it cannot be said that heretofore the various sovereignties of the earth have succeeded in bringing the subject of health within the domain of international law, although there have been a few international medical congresses. All these, though imperfect, in their results have tended to open the whole subject now before us.

At the seventh annual conference of the Association for the Reform and Codification of the Law of Nations, held August, 1879, at Guildhall, London, Sir Sherster Baker, Bart., of Lincoln's Inn Fields, barrister at law, delivered an address on International Rules of Quarantine. From it I glean the following historical memoranda on the subject. Holland has little or no quarantine. Austria has a very severe one. In England a bill was passed in 1825, but it is not called

into requisition, except in epidemics of plague, yellow fever, and cholera. The Port Sanitary Authority, according to a bill passed in 1875, is all that is deemed necessary. But a general law, applicable everywhere, is needed. It should be so uniform as to be capable of international adoption. The writer then gives the following account of various efforts to bring about such an international result. In 1838 France proposed a meeting of delegates from nations bordering on the Mediterranean. Austria opposed the plan, and it was given up. In 1843 Lord Aberdeen sought to bring about such a meeting, but again it failed, owing to the opposition of Austria. In 1851, on invitation of France, an International Sanitary Congress met at Paris, in order, if possible, to obtain a uniform code of quarantine law. France, Great Britain, Austria, Russia, Sardinia, Tuscany, Papal States, Naples, Turkey, Greece, Spain, and Portugal had representatives. All had territory or interests on the Mediterranean Sea. Plague, yellow fever, and cholera were defined and international sanitary regulations were adopted. But only France, Sardinia, Tuscany, Portugal, and Turkey adopted them, because the conference tried to introduce a procedure, which was inconsistent with the laws of some of the countries taking part in the conference. At the end of five years the five named nations also gave up the plan. In 1859 France again made an effort, but failed. In 1865 cholera appeared. In 1866 France suggested a meeting at Constantinople. It was held. All the European states, with Egypt and Persia, were represented. This did much for the prevention of cholera. Finally, the Austro-Hungarian government called a congress at Vienna in 1874. This was not successful, although it tended to promote more cordial union in certain ways. But they all failed because of interference with the rules of quarantine adopted by different nations. The writer lays down certain rules which he deems proper, and which are included under forty articles.

I take the ground that the time is fast approaching, if it be not already at hand, when it becomes the duty of every civilized sovereignty to initiate measures looking to a definite inauguration not only of a national, but also of an international, sanitary code. Each sovereignty should establish its own national board of health. This should have a certain power over the sanitary arrangements of all the states and nations included under that sovereignty. While carefully overlooking its own domain, it should jealously guard its nation from all dangers of infection or contagion from abroad. It should also be prepared, so far as it can do so consistently with the interests committed to its charge, to cooperate with other nations for the promotion of a common public health law. I hold that as civilized states combined to put down buccannery, piracy, and the slave trade, so nations may rightly unite in mutual defense against violently infectious or contagious diseases. They should also exercise the right of compelling uncivilized states to submit to that amount of sanitary law, which may be deemed necessary for the health of mankind. If, for example, any sovereignty allows vast numbers of human beings to collect together at fairs or holy pilgrimages, etc., which are found to be spreaders of disease over the earth's surface, there should be an international sanitary code to prevent such disasters, in the same way that laws now exist to prevent any persons from spreading rapine and plunder over other people.

¹ A paper read before the Boston Society for Medical Improvement, December 8, 1879.

BUT HOW SHALL SUCH A CODE BE COMMENCED?

This end must be brought about by consultation between representatives of various sovereignties, who, after meeting and discussing general sanitary measures, shall lay down a few simple but broad rules of conduct, mere axioms so to speak, to which all the contracting nations would readily agree. Each sovereignty would have the right to reject or adopt one or more or the whole of the propositions. If a single proposition were adopted by all, or even by a large majority, the commencement of an international code would be made which would bind all, and which would be capable of indefinite expansion under the experience of years.

To bring about this international representative meeting, one sovereignty, as has already been repeatedly done, might very properly invite others to join with it and to send representatives to such a congress. No sovereignty has a greater right to inaugurate such a movement than these United States of America. Nay, more, it seems to me that our government ought to deem it one of its highest privileges to be able to present this matter most forcibly to the nations of the earth, and I base this opinion on the following reasons:—

First. Because our government was established and is kept in existence by the people for the good of the whole people, and therefore any measure tending to the moral or physical well-being of any nation ought to be one in which our government and all its citizens should take the liveliest interest, and if need be lead other peoples. *Second.* For want of sanitary knowledge and of an efficient international sanitary code of ethics and of law, we have very many times, within the past third of a century, had our domain encroached upon by a foreign invader as horrible as if in times of peace a hostile army had crossed our borders and spread death and destruction in its pathway. Epidemic cholera, largely depending on filth and reckless disregard of sanitary rules amongst ourselves, has boldly come upon us. It has destroyed our citizens by thousands. We did nothing to prevent its coming, although we plainly saw its gradual approach. After it struck us we were powerless to meet the evil. Whether we consider yellow fever as a disease of domestic or of foreign origin, it seems undoubted that it is carried from one place to another by human migration; and how many times during the past century have we freely opened our ports, filthy in the extreme, and therefore fit receptacles for and fomenters of this terrible disease! All these horrors might have been prevented, and they will eventually be prevented when efficient national and international sanitary codes have been established and obeyed. Surely these warnings ought to arouse Congress to do something towards the prevention of like disasters by international friendly consultation, or if need be by the force of national and, if possible, by international law, so far as it can induce other civilized nations to cooperate with America. Such high contracting parties ought to be allowed to blockade, if necessary, any ports which send forth infectious and contagious diseases, as much as England and America had a right to blockade the shores of Africa to prevent the horrors of the middle passage. It may be claimed, and with justice I think, that *a priori* we should have more right to blockade Cuba than Africa, because slavery did not destroy our people, and by some was believed to give aid to us. But yellow fever cannot claim in the slight-

est degree even such doubtful praise. *Third.* Another reason why Congress should inaugurate this movement is the fact that by its generous confidence extended to the National Board of Health, at the late extra session, it enabled that board to grapple with and almost wholly to confine the late epidemic of yellow fever to Memphis, where it first broke forth in fury. Certainly the board's efforts, which were only possible when backed by the whole power of the nation, have been the main instrumentalities which have averted a wide-spread epidemic, such as swept through the Mississippi Valley in 1878. This much may be justly claimed as the joint result of the generosity of Congress and the action of the board, even while we give all praise to the various organizations and sanitarians of the valley, whose labors were immense. May we not hope that these, with other reasons that might be brought forward, will have some influence upon Congress, and induce it to take the necessary preparatory steps towards bringing the whole subject of sanitation into the domain of international law?

NATIONAL SANITARY ORGANIZATION.

A complete sanitary organization of a nation is at present unknown. England, France, the German Empire, and perhaps we may add Italy and America, are at present groping in that direction,—experimenting, as it were, upon the proper methods to be pursued. In this brief paper I can of course make a few suggestions only, born of my experience during the past few years and from watching the desultory attempts at sanitary order made by various peoples and states. The following schedule of a plan for a national organization is prepared simply as a subject for argument, although I confess I am an earnest advocate of its main principles.

A MINISTER OR SECRETARY OF HEALTH.

Without a fitting government of the sanitary matters of a nation no perfect public health can be procured. Power must be lodged somewhere, and it seems to me a self-evident proposition that a cabinet officer, the peer of all the chiefs of the various departments of government, is indicated, and that in him should be vested that power, under restrictions to be hereafter noticed. This officer should be the presiding genius of the whole movement. In theory, at least, he should be the first sanitarian of the country, and a young or at least a middle-aged man, one of its ablest and most honored citizens. He should hold his office from the national executive, whether it be a republic, kingdom, empire, or other national sovereignty. He should reside at the seat of government, and have a salary equal to that received by other officers of state. He should have the right in great emergencies to summon sanitarians from various parts of the country to consult upon the best interests of the states, territories, departments, or other divisions of the country. But this secretary or minister would be at times called to take prompt action, bearing not only upon the public health, but upon the great commerce of a part or of the whole of the country. It therefore seems to be appropriate, if not actually necessary, for him to have an advisory council, near at hand and always accessible, upon whom he could call for advice and support, and without whose active support he could take no important step. Hence arises the necessity for a

NATIONAL BOARD OF HEALTH.

The members of this board should be either residents at the seat of government, or so near to it that in a few hours they could be summoned to council. It should consist of individuals carefully selected by the sovereign executive of the country from the various departments of the government, and therefore would not receive extra pay. With them might be joined two or more citizens, one of whom at least should be a physician. It would, of course, be important that all should feel interested in promoting the public health. The citizens of the board should receive, while on duty, payment commensurate with the importance of their task and the character of the nation employing them.

In the United States the representatives of the following departments would very naturally be selected: one from the department of state, one from the army, one from the navy, one from the marine hospital service, one from the department of justice, one from the department of the interior, one from the signal service. These, with the two civilians, would make a body of nine persons representing all the various interests of the country. The secretary of health should preside at the meetings, and have full rights of voice and of voting possessed by other members. The board should have meetings quarterly, or as much oftener as it saw fit, and the secretary or minister might summon them to meet on any emergency, or as he might deem necessary for the public welfare. He should lay before them at each quarterly meeting an account of his own work and a statement of the sanitary needs and condition of the country. The board should confirm all doings of the secretary, and by a two-thirds vote of the whole board should have the power to veto any proposed action of the secretary, in which emergency an appeal to the sovereign executive should be made, who, with the secretary, should have full power, and would be held responsible by the country for the proper use of such power. In the intervals between the meetings of the board the secretary should have sway. The board might by a unanimous vote inaugurate any sanitary measures it might deem best, and direct the secretary to carry all such measures into execution; provided that in case there should be a disagreement between the secretary and the board the national executive should decide what should be done. The members of the board should hold office for six years, with the privilege of being again selected by the executive, the first terms of service being so arranged that ever afterwards one member's term of service should expire each year.

EXTERNAL RELATIONS OF A NATIONAL BOARD OF HEALTH.

One of the most pressing of these questions at the present time is the inauguration of a system of international sanitary law. The board should urge upon government the importance of taking some action in the premises. It would be the most fitting body in this country, either by itself or in conjunction with the Academy of Science, to present one or more candidates to the executive as fit representatives of the country in any international congress that might be proposed. And, generally, it should overlook all the sanitary relations of the nation in its intercourse with others.

INTERNAL RELATIONS OF A NATIONAL BOARD OF HEALTH.

It should immediately after its inauguration enter into correspondence with all state or department boards of health, urging them to a thorough sanitary organization of each township, parish, or department within their jurisdiction. It should keep a constant watch upon every portion of the country, and learn the exact sanitary condition of every locality; for by such knowledge alone could it safely guard the whole nation. It should have frequent intercourse with the various state or other large boards having control of large districts. It should call upon each State Board to nominate one of its number as its representative for a national council. If no state boards should have been legally established, it should immediately appeal to each government to establish a board of the highest character.

It is very evident that, under a wise minister of health and the influence of such a board, the intercourse between the national and state and departmental boards would become more intimate each year.

SANITARY ORGANIZATION OF A STATE OR DEPARTMENT.

Its object should be distinctly for sanitary work, and for nothing else. To mix sanitary matters with any other subject is worse than absurd; it will probably be fatal to the best interests of both. The experience of Massachusetts is full of instruction on this point. For years, the Massachusetts Board of Health consisted of seven members, one of whom was the secretary, a salaried man, but having an independent vote, as any other member. Two physicians, one lawyer, one engineer, and two business men, with this secretary, composed it. The board met quarterly, or as often as necessary, and summarily, efficiently, and harmoniously labored chiefly for two objects, namely, the sanitary education of the people, and the sanitary management of offensive trades, etc., in various parts of the State.

Last year, for political and supposed economical reasons, the boards of health and of charities were both abolished, and one board, entitled the Board of Health, Lunacy, and Charity, was substituted. In other words, two entirely new subjects were put with sanitation. One of them, charity, is wholly foreign to sanitary work. The other, lunacy, is not necessarily connected with it, although not so entirely alien as the first. The care of the charities of the State occupies nearly the whole time of the monthly meeting, and would prevent almost all sanitary work, if the board had not committed that portion of its duty to the care of three members of the former board, who now virtually constitute the whole Board of Health. But even this is not strictly true, because all the doings of the three departments of health, lunacy, and charity must be reported, discussed, and perhaps set aside by the full board.

Again, the two secretaries of the Board of Health, who have held office since its formation, have been the first sanitarians in the State, and equal to any in this or in any other country. They have been, till this new arrangement, members of the board, with full powers of voting and of speech. They felt responsible for the action of the board, and keenly alive to any and all proposed doings of the board, and they approved or opposed any measure according to the dictates of their own judgment, and without let or hindrance from any source. Of course, they added im-

mense force to the board. Strangely enough, our new Board of Health, Lunacy, and Charity deprives the secretary of all this responsibility, and makes him a mere hireling, to obey the behests of men, no one of whom knows one tittle that he does on sanitary matters. The most absurd proposition may be made, but he must be dumb, or be deemed impertinent if he gives advice to his *superiors*. He is virtually under bonds, of a salary of twenty-five hundred dollars a year, to keep silence for fear of giving offense to those who hold his office in their hands. Fortunately, the board has a secretary, at present, whom all respect and believe in. His opinion, at times, is sought for and given. But if, by any accident, a man should hold office hereafter simply for the money, sanitary science would, I think, soon lose its prestige in Massachusetts.

To sum up the whole matter, we deem the present junction of health, charity, and lunacy in one board as grotesque a combination as it would be for a physician, a lawyer, and a clergyman to be compelled to work together, and to carry on their three professions in one office, each by its own representative, but restrained and perhaps wholly set at naught by all three meeting together to vote as to all acts. This proposition doubtless seems to you absurd, but it is not a whit more preposterous than the combination called the Massachusetts Board of Health, Lunacy, and Charity.

We have dwelt longer on this experience in Massachusetts because we have felt that its evil example should be held up to the reprobation it richly deserves. It is to be hoped that under a future legislature the Board of Health will be restored to its former untrammelled position. And let every State learn from the present position in Massachusetts to avoid all such entangling alliances between sanitary and any other work, however good. And let us hope, moreover, that all governments will learn from Massachusetts to eschew any false economy in regard to the noble mission devolving upon all state boards of health in their guardianship of the public health.

As originally founded I think that the Massachusetts Board was well organized. It would be well that one of the physicians should be a practical chemist, as every year numerous chemical questions arise. Considering also the importance of the health of animals used for food, a scientific veterinarian might very properly be added to any state board.

A board should select its own president and secretary. The latter might and usually would be one of its own number, but if chosen from abroad he should, on assuming office, take all the privileges enjoyed by members of the board.

DUTIES OF A STATE BOARD OF HEALTH.

The sanitary supervision of the State should be its chief aim. It should educate the people in sanitary matters; teach them to build their houses appropriately, and how to keep them and their own bodies in a sanitary condition. It should have power summarily to abate or put under surveillance any establishment creating a nuisance, but which the smaller or town board feels unable to cope with. It should as far as possible prevent pollution and sophistication of the people's food and drink. It might issue circulars on all sanitary matters, and by having them sent broadcast over the State do an immense service. It should also by annual reports endeavor to advance the general knowledge of sanitary law and of preventive med-

icine. It should urge the organization of town and municipal boards of health throughout the State, and be in frequent communication with them, and for that purpose should have a correspondent in every town, who, in behalf of the board, should act as sanitary inspector of every locality within the limits of the township or parish. It should assist local boards, if need be, with the larger powers of the State. It might act as umpire between the sanitary authorities of two or more adjacent towns. It might organize a corps of lecturers who would discourse on sanitary matters in the various lyceums of the State. It should appoint one of its members to act as delegate when called upon by the National Board for consultation.¹ It should select a correspondent in every township, town, or village in the territory under its control. These persons should be very carefully chosen with reference to their special fitness for the sanitary inspection of a locality. Usually they would be physicians, but not necessarily so, for, at times, a layman may better serve the State. It would be the duty of a correspondent to act as general sanitary inspector of his locality. He should report all local nuisances to the local board, and in cases of a more formidable character, or beyond its powers, he should report the facts to the State Board of Health for its action. Finally, the board should perform any and all other acts consistent with the laws of the commonwealth tending to the promotion of the public health.

If we judge from the experience in Massachusetts, the sovereign power will be ever ready to increase the authority of a board which appropriately and unselfishly devotes itself to the highest sanitary welfare of the State. Almost annually since the formation of such a board in Massachusetts has some new law been enacted confiding more and more summary power to it.

COUNTY OR DEPARTMENTAL BOARDS OF HEALTH.

Still lower in the sanitary organization of a State might legitimately come a county or departmental board. I am not prepared to urge this division of labor, but it is well to meet the question whether such a division might not, at times, be of great use in some States; for example, where there are few large towns, but small hamlets are dotted all over the land. It would have the supervision of the health of a district several miles in extent, whatever kind of districts they were into which the State might be divided. It would have for its objects similar work to that of the state board, but over a less extensive field. It would tend to harmonize the various sanitary doings of the different municipalities within its limits. It would overlook and try to remove all sources of nuisance in one town causing annoyance in another. It might act as umpire in disputed points argued between two adjacent municipalities. It should consist of at least three members, selected from residents in the county or department by vote at a gathering of delegates from the several city and town boards of health. Each should hold office for six years, except that in the first selection one member should be chosen for two, a second for four, and the third for six years. Each might be reelected as long as his constituents should see fit

¹ These summonses would be perhaps infrequent, but it obviously might be deemed very important for the Health Secretary or the National Board to be able to summon experienced sanitarians from each State or department for consultation on important measures bearing upon the welfare of the nation. The traveling expenses should be paid and per diem salary should be given in this case from the national exchequer. It might be legitimately styled the "Health Council of the Nation."

to do so. The board should have close relations with the State Board of Health.

CITY OR TOWN BOARD OF HEALTH.

The number of persons necessary for this part of a state organization might depend (a) upon the number of inhabitants in a place, and (b) upon the extent of its territory. Three would seem as small a number as would be possible for the proper performance of duty in any locality. One of these should be the correspondent of the State Board of Health. The others should be chosen by the citizens or by the mayor and aldermen of a city, for a period of six years. At least one physician should be a member of the board.

This board should have absolute authority to search out and abate all nuisances, with the right of appeal to the state board. The cleaning of streets, overseeing of sewers, the suppression or regulation of noxious trades, etc., would tend to keep its eyes open to all harmful influences bearing upon the health of the municipality.

It should have a corps of inspectors to aid it in the discovering of nuisances and in keeping the city or village up to the highest level of cleanliness. It should be vigilant, and have sufficient means to carry out its plans. It should make sanitary surveys of the place as often as might be necessary, and prepare legislation, if need be, to meet obvious sanitary wants. It should make annual reports to the city or local authorities, and, if need be, ask for legislation of the state government. It should enter into close relations with the State Board of Health. They should mutually assist each other. Members should hold office six years, and one or two should leave each year, as in the county boards. In case the place were large enough to require five persons, two physicians, a lawyer, and an engineer or chemist should be selected. It should choose its president and secretary, the last of whom should be a paid officer, and, if necessary, give his whole time to the board.

THE INDIVIDUAL.

As public health is nothing but the aggregate of the health enjoyed by all the individual members of any community, this question not only is legitimate, but really is a fundamental one in the more general discussion. A man may not only be diseased himself, but he may also become the cause of disease in others. Now, then, can he keep himself in such perfect health as to avoid suffering himself, or bringing it on others?

The first and most obvious remark to be made is that as cleanliness is the most important element towards a perfect sanitary condition of a locality, so it is with the individual man. Cleanliness of body, cleanliness of disposition, and clearness and calmness of intellect comprise the chief, if not the only, elements necessary for human health.

By cleanliness of the body we do not mean a simple daily ablution of the face and hands, and an occasional full bath; but we mean a *daily bath all over the body* with pure water, sometimes using a little soap, and always using it for *certain* parts.¹

But cleanliness of the skin does not make a man clean, except in one great system. If he wish for perfect health, he must attend closely to his digestion. He should not overload his stomach, even with good things. A gourmand can hardly be said to be in a perfectly healthy condition; and any one, even a devout anchorite, who neglects to clean his internal *prime ræ*, as they are styled by the earlier physicians, is dooming himself to ill-health of body and to a disturbance of his morals and mind. The old saying, "Fear God and keep the bowels open" comprises the whole duty of man," may be objected to by some moderns as untrue. Yet there is no more sacred truth than this, namely, that a daily freeing of the body from the effete matters on the skin and in the alimentary canal is essential to individual health, and hence also to public health.

And here let us add one word on the question of beverages for man. Undoubtedly there are persons who can be water or milk drinkers all their lives, and need nothing stronger. We believe that it is rare that the young need anything like stimulants for health; hence it is wrong to use them. Some persons, later in life, find it necessary to use a small amount of wine, or beer, or other even stronger liquor. And provided these be used moderately and simply, to meet an obvious necessity, no evil ensues. But if at any age, for any purposes and under any circumstances, a person indulges to inebriation, nothing but evil can result. Every man knows this by his own feelings after a night of debauch. His clouded intellect, his laggard, non-elastic step, and his general malaise of mind—all prove this to anybody but an arrant simpleton. When the habit becomes chronic, nothing but mischief comes to the individual and to the community. Individual life becomes miserable, the family suffers cruelly, and the public health is impaired. "Total abstinence," in such cases, is the only safeguard for the man, the family, and the public, and "prohibition" to the *drunkard*, becomes the highest sanitary duty of a State, provided that any prohibitory law can meet the emergency.

We ask, then, for pure water for the majority of human beings. But in how few homesteads in this country have proper precautions been taken for securing perfectly pure wells! How many persons place their privies, their cow-yards, or their house drains so near to their wells that it is utterly impossible to avoid contamination. Some wells, in some soils, will drain a cone more than a hundred feet in diameter at the surface of the ground.

PURE AIR AND HEALTH.

When selecting a site upon which he hopes to rear a family, let a man avoid a damp soil as deadly in its influence. This law of dampness of soil and air, especially in its influence upon the production of consumption, is now as certainly proved as the law of gravity. We must accept it and avoid it, or take the consequences. Of two families, one born and reared on a damp soil will be from two to three times as liable to die of consumption as another born and reared upon a dry soil. Yet how few fathers ask about the soil! for, provided the site be agreeable to the eye, or for other reasons, the point of the healthfulness of the place in this particular is wholly ignored.

part before proceeding to bathe another, he could succeed in accomplishing a full bath daily and comfortably with excellent hygienic effect, even in the coldest day in winter.

¹ For this bath nothing more is needed than a hand-basinful of water and one towel. This, though doubtless far less fascinating than some of the fashionable Roman or Turkish baths, is the only one which can be indulged in alike by the beggar and the king. Without it we cannot reach the whole people. With it, and with his own hands to apply the water, every man, however humble, can enjoy all the real advantages of perfect cleanliness of the skin. By using the hand instead of a sponge, by thoroughly wiping and covering one

How many parents, otherwise most kind and thoughtful, allow accumulations of water in the cellars of their homesteads! They wonder at the poor health of the household, and talk about the providence of God being somehow the cause of the difficulty, whereas it is owing to their own ignorance or willful violation of health laws.

Again, how many adults and how many children are daily submitted to the rebreathing of the air that has been used many times in the school-room, workshop, store, warehouse, kitchen, or parlor?

Men seem to forget that pure air in piteous streams is needed for the perfect health of man. Go into our public assembly rooms, our courts of justice, or our churches, from the external air, and see if you are not oppressed by the noisome vapors, which the folly (or crime, as it seems to me we may sometimes call it) of our public authorities compel our people to breathe, often to their infinite injury.

The time will come when our descendants will look back with horror and disgust at the thought that such a building as the Boston Court House should have ever been built, and still more at the fact that, notwithstanding the annual and piteous complaints of sufferers, who are among our noblest citizens, and who are engaged in the most important public duties, the city authorities should steadily refuse to grant any change.

THE MIND.

A healthy mind in a healthy body is always considered the richest boon bestowed on man. When one can use his mind for real mental work, as he would a sledge-hammer in physical labor, then, and not till then, is a man in perfect health. And in order to have this stalwart condition, he must have all the bodily organs go on smoothly, and without his being aware of any of them save in their regular performance of necessary functions. How many have this delightful state of feeling?

Owing to several causes, among which may be cited as prominent our institutions, the inventions of modern times, enabling us and rather leading us to work *heroically*, and finally our exhilarating atmosphere, etc., almost all the community, young and old, *overwork*, and the result is that our children break down at school; our middle-aged finish their labors, or some have to rest for months, perhaps, when without such overwork their minds could have continued active for an indefinite period of time; others become prematurely aged.

We have thus glanced at the skin, the digestive system, the thorax, and the head, and we have hinted at some few of the evils now pressing upon us all, and causing injury to the public health. We believe that the scientific sanitary culture now going on will either overcome or greatly alleviate them. We have forborne all allusion to other tendencies, which, if followed with reason, elevate, refine, and physically improve both sexes, but which used unreasonably and immorally are likely to bring not only unutterable mischief and sorrow to the violator of law, but woe upon their descendants.

We have accomplished our purpose if we have led even a few minds seriously to reflect upon the importance of having among all nations well-devised sanitary organizations, which, beginning with the individual himself, will endeavor to teach him the rules of health, and afterwards will guard him from various dangers to

which he may be exposed from his own neighborhood, from the State, the nation, or from mankind, outside of his own people.

LITHOLAPAXY.

AN IMPROVED EVACUATOR.

BY HENRY J. BIGELOW, M. D.

Professor of Surgery in Harvard University, Surgeon of the Massachusetts General Hospital, Boston.

THE operation for the complete removal of a stone at one sitting, by crushing, has been as successful as its most sanguine advocates could have hoped. Several years may still be needed to determine precisely its relative value; but in the mean time it has been abundantly proved that the bladder tolerates long operations, provided the fragments of the stone, which are the principal cause of inflammation, be removed,—and that fragments need no longer be a source of inflammation. Although several cases of litholapaxy have terminated fatally, the cause of death was not the usual one after such operations: it was not an inflammation of obscure origin, connected with previous disease of the bladder or of the kidneys. The few deaths that have occurred were due to mechanical injury, which, with greater experience in operations of this kind, will doubtless, in the future, be avoided.

It has been remarked by more than one writer, that the new lithotripsy requires even more care than was necessary in the old method by short sittings. This is true. Each repeated act of crushing or of evacuation is obviously liable to its own casualties, and we must add to this liability any that may arise from the gradual abatement of the operator's vigilance. It was once an object, in persuading surgeons to forego their traditional prejudices, to show that the new operation was safer than they supposed; but this being now generally conceded, it is at present important to insist that it should be attempted only by practiced lithotritists, or by a beginner only after familiar practice upon the cadaver. I know no other surgical operation in which a little want of skill or of care is so insidiously liable to fatal accident. The skill here is of a particular kind; and though a surgeon may use a knife well, it does not follow that he also uses a lithotrite well. Before considering this instrument, however, let us examine the evacuator, or "wash-bottle."

It was an alteration of this instrument that made litholapaxy possible, and led to the discovery of the tolerance of the bladder. This was the enlargement of its tubes from the size of the common catheter to the largest the urethra will admit without injury. In evacuating a small stone the smaller of the new large catheters (26 or 27 French) works well enough; but in order to evacuate a considerable stone with comfort either to the surgeon or to the patient, we need a catheter of from 28 to 31, and for its introduction it is often well to enlarge the meatus, which is the narrowest part of the urethra. I cannot but think that the preference of some operators for the curved tube I at first employed is connected with their previous familiarity with curved catheters. And yet when a curved evacuating-tube is in position, its entire curve is in the bladder; and in the manipulation of the instrument there exists the disadvantage of not seeing, as readily as with a straight tube, where its point lies. The orifice, in either case, is on the side of the extremity, and

there is perhaps a quarter of an inch of tapering solid metal beyond it, necessary to make its introduction easy, and to keep the bladder from obstructing it.

The large evacuating-tube being the essential instrument in the new operation, a vacuum produced by almost any apparatus will draw fragments through it. Certain principles, however, observed in their construction, will make them more convenient and efficient.

An apparatus I early employed consisted of a stiff bulb and Clover's trap, attached to the large catheter by a short elastic tube. The combination was a good one; for the elastic tube allowed the bulb, when in use, to be bent down to the level of the bladder. The bulb could also be laid on its side, and, by further depression, reversed; which brought the catheter tube to the top. It then remained only to open a trap at its lowest point and the fragments remained where they fell.

This arrangement, placed in a stand, is practically the evacuator I still use.

A strong bulb or bottle is here a very desirable substitute for the former slender one.

In the glass trap at the bottom of the instrument, the fragments are kept out of the current at a point distant from the catheter. After entering at the top of the bulb, they settle at once to the bottom and remain there undisturbed.

If fragments are drawn through the tube with the force and rapidity that are given to the current by a strong elastic bottle, a few inches added to the length of the route are of no consequence. A short and curved elastic tube (here five inches long, but which I have varied from two inches to two feet) between the bottle and the catheter makes it possible to move one without the other. It relieves the surgeon and protects

FIG. 1. — A. Glass trap, forming, with the screw-catch B, which supports it on the stand, a ball-and-socket joint.

C. Elastic bulb or bottle.

D. Elastic tube, five inches long. One end is attached to E, the evacuating catheter, and the other is continued into the bulb to form a chamber above its orifice.

F. Coupling between the cocks of the evacuating catheter and the elastic tube.

(TIEMANN & Co., New York.)

the patient. The surgeon can explore the bladder in search of fragments, without having to move the bulb which weighs a pound or two; while the jar of pumping does not reach the bladder. The discomfort to the unethersized patient resulting from this jar is a serious objection to the rigid attachment of the bulb of water to the catheter. It should have a support of its own, placed upon the table or bed between the patient's legs, which may be separated a little, as in the case of the introduction of a catheter or a lithotrite. The surgeon's hand, instead of supporting the water bottle, is then supported by it.

The bulb, when thus near the level of the bladder, acts as a siphon. This is desirable. By experiments you will find that the difficulty of suction increases as the bulb is held higher than the evacuating-tube. It is very marked in Clover's instrument. There is great

advantage in keeping the bulb low, near the level of the bladder.

The evacuator thus described works very well. I have used it in most of the operations you have seen. Its imperfections are that if, by accident, a little air gets inside the bulb, this has to be uncoupled to get rid of it, and a few drops of water may escape in coupling and wet the bed. By a simple expedient I have remedied these inconveniences. In the instrument I here show you, air can be removed, or water withdrawn from the bulb, or added to it, without a drop being spilled. Indeed, the operation would be absolutely dry, did not a sensitive bladder occasionally contract and squeeze out a little water by the side of the lithotrite or catheter, in spite of the elastic band I usually tie around the penis to prevent it. When this happens, it is perhaps best not to try to stop it.

In this instrument, the large evacuating tube at the top of the bulb extends an inch or more downward into its cavity. A space is thus formed where any accidental air collects, but cannot pass to the bladder. This space is emptied at will, through another elastic tube or hose, a little more than a quarter of an inch in diameter, placed by the side of the first. The arrangement is a very simple one. Through this small hose, which can be attached and detached in a moment, the turbid contents of the bulb may be replaced by clear water, without unfastening it from the catheter; or the contents of a tumbler can be transferred to the bladder, and hack again, absolutely without loss of water and with the elimination of all the air. With one end of the apparatus in the bladder and the other in a basin, the operator, even while he is evacuating the fragments, can vary the volume of water at will and put it where he pleases. The catheter, and the elastic tubes, large and small, are each provided with a stop-cock.

If, before using the lithotrite, the surgeon desires to add or withdraw water from the bladder, this may be done through a common sized catheter coupled with the bulb, — thus obviating the necessity for a syringe, and rendering this part of the operation as dry as the rest.

Instead of the metal ball-and-socket joint in the stand of my former instrument, I have substituted another, of which a strong glass trap forms the ball. This is supported in a metal socket, which allows all necessary motion, or fixes it upon the flat disk.

The operation is as follows. Before a catheter is introduced, its stop-cock must be closed. The urine is drawn through a small catheter and replaced by water from the bulb. The lithotrite is then introduced, and the stone is crushed. A large catheter is next passed into the bladder, to evacuate the fragments. If, during the pumping, the bladder indicates, by repeatedly stopping the catheter, that its parietes are hanging loose and acting as a valve, it should be distended by a little water injected from the bulb. This water is retained in the bladder by closing the cock of the catheter; while the bulb is replenished through the small hose.

When the empty evacuating catheter is first introduced, a few bubbles often rise from it, and are caught in the bulb by elevating it. But when the current is established, air takes care of itself, and goes to the trap in the top of the bulb. In fact, there is none, unless by accident. By opening all the cocks, and compressing the abdomen, it is easy to drive air out of the bladder through the bulb as far as the basin.

In pumping you need move only a couple of ounces of water between the bladder and the bulb, backward and forward, gently, without a jerk, once in a second or two. The tube is advantageously held just off the floor of the bladder, — a little higher at first, when the debris clog it, and lower down when only a few fragments remain.

As regards the amount of time necessary for an operation under either, take as much as you please; precisely as you do in an amputation or excision. I usually add to the evacuation a thorough sounding. This requires more time. Some operators leave a few fragments in the bladder, to make the sitting shorter, but I doubt the expediency of doing so. Great care is essential, — also practice. Learn from a good instructor how to pass instruments, large and small, curved and

straight, with absolute facility, upon the dead body, before practicing upon the living. Notwithstanding an occasional assertion to the contrary, I assure you, that, if you can introduce with ease into the bladder of a dead subject, not empirically, but with a reason for each movement, a common tin sound bent successively into a variety of different irregular curves, (and a few hours' intelligent practice, based upon anatomical considerations, will enable you to do this,) you will handle a catheter adroitly in any difficult case upon the living subject, and avoid the accidents that sometimes follow the introduction of common instruments, such as laceration of the mucous membrane and false passage; you will also be able to deal skillfully with obstructions from strictures or the irregular walls of an enlarged prostate. Certain accidents with the lithotrite, however, deserve special consideration.¹

THE COMMITMENT OF THE INSANE.²

BY BENJAMIN CUSHING, M. D.

THE public mind has lately been excited on the subject of the commitment of the insane to asylums. It was thought that personal liberty was not sufficiently guarded. An application signed by the "next friend," notice to the mayor or selectmen, and a certificate, signed and sworn to by two physicians, were enough, in Massachusetts, to warrant the superintendent of an asylum to receive and hold in custody one charged with insanity. In some States much less is required.

¹ The evaluator of Thompson illustrates the objections mentioned in the text. *Latterly* (Gazette Hebdomadaire, Oct. 31, 1879), Thompson has arranged a single cock to do the duty of two in closing the lower bulb orifices to keep the bed dry. But the instrument is virtually the same. (1.) The bulb, or bottle, like Clover's, is above the catheter, so that the water has to be drawn up into it, and, if the cocks happen to be simultaneously opened for a moment, it will all run into the bladder and distend it. (2.) Its weight must be supported by the operator, or rest upon the catheter. (3.) Being rigidly fixed to the catheter, it communicates the jar of pumping to the bladder; this old "short connection" thus retained between catheter and bulb, upon which Thompson insists, yielding, so far as I can discover, no equivalent advantage. (4.) Lastly, the mouth of the catheter enters low down, into the narrowest part of the bulb. Consequently fragments, after rising into the bulb, with the current, must, on their way to the glass trap, again crowd in front of the catheter; and thus debris are needlessly returned to the bladder. It would be better, if it be desired to connect the catheter low down, to prolong it a couple of inches inside the bulb, and to let the fragments escape at a higher point, where the cavity is wider, as is represented in the lowest tube of the annexed diagram. With such an instrument I experimented some time ago. (Fig. 2, 1.) This arrangement also keeps the contents of the trap quiet, and there is no return of fragments.

But even an imperfect or inconvenient apparatus may suffice to empty the bladder. The only feature of an evaluator absolutely essential to rapid lithotripsy is the large catheter I have elsewhere described, which Thompson has adopted without change. It is this that enables his instrument to evacuate. The want of this large catheter (in combination with good suction and a trap) was fatal to the success of previous instruments, and to all attempts at the immediate evacuation of any considerable amount of débris. With such a catheter, Clover's instrument could have evacuated the bladder slowly, and might have led, in the face of traditional prejudice, to the discovery of the tolerance of that organ, and of lithotripsy at a single sitting. But the catheter of Clover's instrument was too small, being only 21 French (12 English), beyond which the English scale did not go. Its eye was also defective. The new method was impossible to those who were using this small catheter. They could not empty the bladder of all its fragments, and therefore knew nothing of the great recuperative powers after the complete removal of this source of irritation. Authorities agreed that evacuating catheters were worthless. When Otis directed the attention of surgeons to the fact (see a paper by R. F. Weir, New York Medical Journal, April, 1876,) that the capacity of the average urethra was very nearly 33, rapid lithotripsy was made easy. Sitzings were lengthened from a few minutes to an hour or two.

² Read before the Dorchester Medical Club.

There remained the power of the superintendent to judge of the propriety of keeping the patient, and the patient himself could, theoretically, take the benefit of "habeas corpus," but practically it might be otherwise. This, by the new law, is changed, and the commitment of the insane is now a judicial proceeding.

Although, on first thought, this seems like taking these cases from the physician and giving them to the lawyer, it is not so. The new law requires a certificate, signed by two physicians, "graduates of some legally organized medical college," and of three years' practice, that the patient is insane and a fit subject for treatment in an asylum. The signers are to appear in court and give reasons for their opinion, and on this evidence and his own personal examination the judge issues a warrant to commit.

I cannot learn that much wrong has been done under the old law, but I can see that it was quite possible, and am inclined to think the new law not uncalled for. I think that I have known of commitments which ought not to have been made and, under the new law, would not be made.

I question whether in the medical certificate, the second point, namely, fitness for treatment in an asylum, has always been sufficiently considered. It is true that the insane must often be confined for the safety of the community, but it is equally true that some of them may be safely and more comfortably cared for outside asylum walls. In truth, I think certificates have sometimes been given too hastily. At any rate such is my own experience and observation.

Again, the old law said "two physicians," and gave no guarantee that the physicians were competent to give an opinion on which so much depended. The new law defines the word "physicians," and subjects the medical opinion to an examination which, if sound, it will bear; if not sound, it will need. The judge also naturally will know the character of his witnesses; and, what is important, proceedings are in open court.

But, while the new law gives new safeguards to liberty, it brings some serious inconveniences to the unfortunate insane themselves, which should be provided against. A case which came under my notice, will illustrate this.

I was visiting a patient when I was told that some one wanted me. Going to the door I found a young man waiting for me, flourishing a club in a violent and excited manner. At first, I thought that he was intoxicated, but soon recognized him as an insane man whom I had formerly known. I took him to his home and advised his immediate removal to an asylum, both for his own sake and because he was dangerous to others, being disposed to be quarrelsome. It was too late in the day to get an order from court to commit him, and I did not like to have him confined in one of the underground cells of the station. Provision was therefore made to care for him in his father's house until the following day, when he might be taken before the judge of probate. On the next morning he was taken by an officer to the city. It so happened that the court did not sit on that day, it being Decoration Day, a fact which had not been thought of, and I afterwards learned that the unfortunate young man was confined for a day and a night in one of the cells under the court-house (I believe they are called "Tombs" and well named), whence he was taken raving and hand-cuffed to South Boston.

From this may be seen what is needed, namely, a suitable place where the insane, who are too violent to be left at large for any length of time, can be detained with comfort to themselves, and not be made worse by a confinement which cannot but aggravate their malady. In this connection let me say that the lock-ups in this State, including those in Boston, are not what they should be. Many of them are under ground and infested with vermin, badly ventilated, and too far removed from the night-watch to be safe for the occupants.

It should be borne in mind that these cells are for those waiting trial, and not for convicted criminals; places for detention, not for punishment. It is a maxim of the law that all are presumed innocent until proved to be guilty. If this is anything but a pleasant legal fiction, the occupants of these cells are in the eye of the law innocent, for they have not been tried. They should not be subjected to unnecessary discomfort or danger. One arrested on suspicion is entitled to be tried and, if acquitted, returned to society in as good condition as before arrest. The State is morally responsible for so much. Under my limited observation, within a few years, several cases of death have occurred, the direct results of imprisonment in our lock-ups.

If our boards of health, state and city, would give attention to this matter and personally visit the lock-ups in Boston and vicinity, and learn their histories, they would, I think, find a field of labor large and, as yet, uncultivated.

RECENT PROGRESS IN GYNÆCOLOGY.

BY W. H. BAKER, M. D.

The Treatment of Epithelioma of the Cervix Uteri.—Dr. J. Marion Sims contributes a most valuable article on this subject to the *American Journal of Obstetrics* for July, 1879, giving the details of ten cases and a description of his method of operating. The steps of the operation are essentially as follows: The patient is etherized and placed in the left lateral semi-prone position; the Sims speculum being applied, the tumor is to be seized with vulsella, pulled forward, and held firmly, while with the curette we remove as fast as possible the soft or outer portion, this being the most vascular; when the underlying or indurated portion is reached the bleeding becomes less troublesome, and the scissors or knife should then be substituted for the curette, and the diseased tissue removed piece by piece until the healthy structure, as detected by the touch, is reached; the parts are then sponged as dry as possible and quickly filled with styptic cotton wool until the conical cavity made in the uterus is firmly packed with it, a few layers of the same dressings being tightly put in the upper part of the vagina, and the remainder of that canal tamponed with cotton wet in carbolic water. The vaginal tampon should be removed within forty-eight hours, except the styptic cotton in its upper part, which, together with that in the neck of the uterus, should be left until the fourth or fifth day; on its removal, the conical excavation of the cervix should be filled with cotton wool wet in a solution of chloride of zinc of the following strength:—

℞ Zinc chloridi	3v.
Aqua distillat.	3i.
M. Ft. sol.	

The upper part of the vagina is to be tamponed tightly with cotton wool saturated with a solution of bicarbonate of soda. The chloride of zinc produces intense pain, and it is always necessary to give morphia hypodermically to relieve it. If the zinc cotton wool be too wet the superabundant fluid runs down the vagina and inflames it.

The vaginal cotton wool may be removed in part the next day, and wholly in a day or two more. But the zinc wool in the cervix is not to be interfered with until the fourth or fifth day, or until it has freed itself by suppuration. When this dressing is all removed, a slough about a sixteenth of an inch thick will be found to line the cervical cavity, which can sometimes be taken out in one entire piece. Beneath it we should see healthy granulations, which heal in from ten to fifteen days under the use of vaginal injections of warm carbolized water.

The operation divides itself into two stages, — that of removing the diseased tissue and applying the styptic cotton for the control of hæmorrhage, and the subsequent destruction of so much more of the underlying structure by the chloride-of-zinc dressings.

One most important point in the first stage, which is strongly insisted upon and which we fear is too often neglected, is that of following up the removal of the disease, even to or somewhat through the *os internum*, instead of amputating the diseased mass at the vaginal insertion of the cervix, as will be shown by the diagram: —

The author advises the internal exhibition of arsenic (Fowler's solution) subsequently, in such doses as shall not interfere with the digestion, and also that the patient should be carefully examined each two months, that we may be sure there is no return of the disease. Should there be any recurrence the curette should be used and the zinc dressing applied as before.

The ten cases reported seem to have been selected by the author to illustrate different stages of the disease or to bring forward some important point in the treatment. This, of course, gives greatly increased force to the article.

It would be hardly fair, however, to draw conclusions from these cases as to the length of immunity from the disease resulting to the patient. But from the fact that two of the patients were doing well at the end of five years we should be encouraged to practice the

thorough removal and destruction of the disease recommended by Dr. Sims. We wish he could have incorporated in his most interesting article the analyses of all the cases of this form of disease upon which he has practiced the above-described operation, for we should then be able to reach a much more definite conclusion in regard to it. The inferences which Dr. Sims deduces from the facts set forth in his paper are: —

"(1.) Do not amputate or slice off an epithelioma of the cervix uteri on a level with the vagina, whether by the *cæteræ* or the electro-cautery.

"(2.) Excise the whole of the diseased tissue, even up to the *os internum* if necessary.

"(3.) Arrest the bleeding, when necessary, with a tampon of styptic iron or alum cotton wool.

"(4.) Be careful not to apply the tampon with such force as to lacerate the excavated cervix uteri.

"(5.) When the styptic tampon is removed, cauterize the granulating cavity from which the disease was excised with chloride of zinc, bromine, sulphate of zinc, or some other manageable caustic capable of producing a slough.

"(6.) After the removal of the caustic and the slough it produces, use carbolized warm water vaginal douches daily till cicatrization is complete.

"(7.) After the cure put the patient on the use of arsenic as a protection against the cancerous diathesis, and urge the importance of examination every two or three months for the purpose of detecting the recurrence of disease.

"(8.) Then if fungous granulations or knobby protuberances not larger than a pea are found, lose no time in removing them, and treat the case afterward with caustic, just as in the first instance.

"(9.) Almost every case may be benefited by operation, even when there is no hope of giving entire relief."

This operation, which we had learned from the personal instruction of Dr. Sims, and the value of which we have learned from our own experience to be very great, has yet certain disadvantages which others have tried to overcome by using Paquelin's thermo-cautery, removing a conical plug from the cervix, as referred to in the above article. The objections to the Sims method are: *first*, the danger of lacerating the excavated cervix in applying the tampon, or of applying it so tightly that when the tissue is very thin there is danger of a slough taking place, whereby the peritoneal cavity may be opened; *second*, that the styptic cotton, if left a few hours too long in the uterus, endangers the patient to septicæmia; and as this cotton in the upper part of the vagina is often sealed tightly in place, even when that in the uterus is free, a certain amount of old blood and pus is imprisoned in the uterus, which sends the temperature up, and we hasten to remove, often with great difficulty, the tightly-sealed portion in the upper vagina, in order to give escape to the purulent collection; *third*, the great tax upon the strength of the patient which the repeated changing of dressings necessitates; and, *fourth*, the pain caused and the damage which is sometimes done to the vagina by the chloride-of-zinc dressings.

The objection to the other method mentioned is that in using the thermo-cautery from the beginning of the operation we cannot thereby be sure that the entire disease is removed.

For the past two years in the several cases upon

which we have been obliged to operate, we have followed the Sims method up to the point of applying the styptic cotton, thereby gaining all the advantages of the sense of touch in guiding us as to the entire removal of the disease. We have then substituted the thorough application of the thermo-cautery at red heat, the patient still remaining in the Sims position, without removing the Sims speculum. By this means we have been able, in nearly every instance, entirely to check all hemorrhage and at the same time destroy a depth of tissue as great as that destroyed by the chloride-of-zinc dressings. We have, moreover, by this means obviated all the objections that we can see to the Sims method, as well as the objections to the use of the cautery for the entire operation; and, by accomplishing the whole essential treatment at one time, we can secure to the patient a degree of rest and freedom from pain, to say nothing of the absence of danger of laceration and septicaemia, which are acknowledged to be present in the Sims method entire, and this, we think, without in any way diminishing the thoroughness of the operation.

Batley's Operation.—Dr. Heywood Smith reports a successful case of extirpation of the ovaries in the *British Medical Journal* for July 12, 1879. The case shown in this report, and especially the full description of the gross and microscopical appearances of the ovaries removed, make it very interesting; and if other operators would take as much pains in the subsequent careful examinations of the specimens removed in this operation we should be able to arrive at a more definite knowledge of the causes which give rise to the necessity for its performance.

The right ovary was small, irregularly oval in shape, the surface corrugated and furrowed by deep sulci. On section, the interior was found to be hollowed out into numerous spaces filled with a transparent viscid fluid. Under the microscope these spaces were most numerous in the neighborhood of the large blood-vessels near the hilus; their shape was irregular, generally somewhat oval in outline. None of them had any distinct cyst wall. They were bounded by ovarian stroma, which in their vicinity was loose, and in some cases retiform. In no case did a cyst present any appearance of being produced by the dilatation of a Graafian follicle; all were evidently new "areolar" formations in the stroma of connective tissue. In several instances there were masses of extravasated blood in the cyst.

The left ovary was similar, only less corrugated, and containing more blood-vessels. Few Graafian follicles were found in either organ.

In his remarks on the case he explains the dysmenorrhoea as follows: "First stage, congestive, but we know not from what cause, physical or mental; second stage, vascular, the vessels becoming almost varicose, their walls thickened by some slight inflammation; the periodic hyperemia producing pressure on the stroma of the ovary and its nerves, this stage accompanied by degeneration of and cyst formation in the stroma; and, lastly, third stage, that of "cirrhosis," when the fibrous nature of the degeneration produced irregular contraction, drawing in the stroma (especially marked on the surface of the ovary), and so maintaining, if not increasing, the periodic pain by the hyperemia acting on the contracted organ not having free scope for that enlargement that would have lessened the eccentric pressure."

Hospital Practice and Clinical Memoranda.

ANTISEPTIC SURGERY.

A SERIES OF CASES REPORTED TO THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

BY H. H. A. BEACHT, M. D.,

Demonstrator of Anatomy in Harvard University, Surgeon to the Massachusetts General Hospital.

Gun-Shot Injury of the Elbow-Joint; Complete Excision of the Joint; Recovery with a Useful Arm.—R. W. P., aged twenty-five, entered the Massachusetts General Hospital three hours after receiving a charge of shot in the joint from the explosion of a gun four feet distant. The joint was torn open, the head of the radius and the external condyle of the humerus were comminuted, while the soft parts on the outer side of the joint were lacerated, blackened, and charged with shot and small pieces of bone. The wound was thoroughly carbolized, and the joint completely excised, the fragments of bone, shot, and loose shreds of muscle and skin having been removed. Sutures were not used, as the contusion to which the parts had been subjected made the probability of considerable swelling a strong one. A Lister dressing was applied, and the limb placed upon an internal angular splint. Considerable sloughing of the soft parts followed, but at the end of the first two weeks the wounds presented a bright granulating surface four inches long by five inches broad. One month after the injury, gentle passive motion was employed, and in five weeks the patient was up and about. Discharged well two months and a half after entering the hospital. Now, he can use the arm, hand, and fingers as well as he can those of the other limb, and is working at his trade, that of a machinist, from morning until night.

Fracture of both Thighs; Compound Comminuted Fracture of the Tibia, Fibula, and Tarsal Bones into the Ankle-Joint; Amputation of one Leg; Recovery with Good Union in both Thighs.—J. A., aged twenty-one, was brought to the hospital two hours after having been thrown violently to the ground by a railroad car, one wheel of which had passed over the left ankle-joint, crushing the bones and soft parts. The fall produced a fracture of both thighs at the middle. The leg was amputated at the junction of the middle and upper thirds, and dressed by Lister's method. Coaptation splints were applied to the thighs, and an extension of seven pounds was attached to the right leg. No extension applied to the left leg. In two months after his admission he had good union. Eleven days later the dressing was removed from the stump permanently, the wound having healed. He was about on crutches for another month, and then discharged well.

Lister's method was of exceptional value in this case, for, in eight weeks only six changes of the dressings were necessary. The immobility required for the repair of the fractured femur would have been seriously interfered with by manipulations of the limb incident to the ordinary daily dressings, and the patient's comfort lessened materially.

Cystic Disease of the Left Ovary; Ovariectomy; Death in Ten Days.—J. M., single, thirty years old, was in fair general condition, though she had become emaciated during the past year. Her attention was directed to the tumor about two years since by pain and swelling in the left iliac region which gradually extended

toward the middle and right side of the abdomen. She was tapped by her physician to relieve dyspnea, and twenty pounds of opaque fluid, so thick that it would not run through the canula, were drawn off through the puncture. Considerable relief followed the tapping, but the fluid reaccumulated, and though no other organic disease could be detected her health had become seriously impaired during the past six months. Her menses were regular. The girth of the abdomen on a level with the umbilicus was thirty-five inches, the parietes, tightly stretched over the cyst. The whole front of the abdomen was dull on percussion, while the flanks were resonant. The uterus was drawn up and tilted to the right side of the pelvis. A large, rounded body nearly filled the pelvic cavity, and could be felt through the vagina and rectum. There was no history of peritonitis after the tapping. Seven days after the cessation of her menses the tumor was removed, with all the precautions of Lister's antiseptic system.

A straight incision of four inches was made between the umbilicus and pubes; on reaching the tumor a firm adhesion was found at the point where she had been tapped, which permitted a partial evacuation of the cyst without introducing the trocar, or allowing any of the fluid to enter the peritoneal cavity. A thick, glutinous, chocolate-colored fluid filled the cyst, and when removed occupied half a water-pail. The incision was extended two inches above the umbilicus in order to reach some omental adhesions. To prevent any escape of fluid during its removal into the peritoneal cavity, the opening into the cyst was closed by a strong double ligature. The pedicle was secured by the Spencer Wells clamp. A few bleeding vessels were tied, and the wound was closed by deep and superficial silk sutures. The pedicle was treated with persulphate of iron, as Mr. Wells directs. A Lister dressing was then carefully applied to the wound. The patient bore the operation well. At night the pulse was 96, and the temperature 100.8° F. On the following day she complained of pain in her back, and her temperature reached 101.8° F. (the highest point after the operation). On the third day she had some tympanites and abdominal pain, from which she was relieved by passing the rectal tube. One week from the day of operation the dressing was removed under carbolic spray, and the wound found in good condition, union having apparently taken place throughout. One half of the sutures were removed, and the Lister dressing was again applied. No change of importance occurred until two days after, when she became quite restless, and complained of abdominal pain. The wound was examined under carbolic spray, and the remaining stitches were taken out. The end of the pedicle had a foul odor; it was carbolized with a one-to-twenty solution. Later in the day she had some vomiting, and a slight enlargement of the parotid gland on the right side was observed. She was restless and somewhat delirious during the night. The pulse gradually failed, and the stomach rejected stimulus. Subcutaneous injections of morphia relieved the vomiting temporarily. This condition continued during the next day, and she died suddenly in the evening.

The friends permitted an examination of the wound only, and I am unable to describe the condition of the joints and viscera. An incision was made into the abdominal cavity, parallel to the wound, and a large flap of the abdominal parietes everted, showing the wound to have healed perfectly on the peritoneal surface and

firmly adherent to the pedicle; not even the trace of a suture being visible. There were no evidences of peritoneal inflammation excepting a patch of faint redness near the line of union. The intestines were free from the anterior wall and not glued together, nor was there any abnormal quantity of serum in the peritoneal cavity. The sloughing end of the pedicle had not become detached, and extending laterally from it beneath the skin was a small pocket containing some foul pus, which might have been the source of infection.

Cystic Disease of the Left Ovary; Ovariectomy; Recovery.—The patient is twenty-six years old, and she first noticed a tumor in the left iliac region three years ago, which gradually increased until a year since, when she had what was called at the time "inflammation of the bowels" from that time the catamenia did not appear for four months. The growth of the tumor continued until nine months ago, when it was tapped and about a gallon of chocolate-colored fluid drawn off. After that, the sac slowly filled again, and she was treated by electrolysis, the needle having been inserted thirty-two different times, and after each insertion there was some pain and tenderness about the punctures for two or three days. Her abdomen was distended to the size of a woman at full term, and the tumor was evidently made up of one large cyst and several smaller ones. The uterus had been drawn over to the right side of the pelvis by the growth. No other organic disease existed.

The operation was performed under carbolic spray. A straight incision of four inches, made in the median line between the umbilicus and the pubes, opened into a chamber of thin, purulent fluid, the result of peritoneal inflammation; the sac was then reached and punctured. About five quarts of fluid were removed, having the same appearance as that evacuated by tapping. The incision was then extended four inches above the umbilicus, as without it a careful dissection of the adhesions could not be made; they were very firm, involving the intestines, abdominal wall, and pelvic viscera. The pedicle, short and broad, was ligatured securely with stout catgut and dropped into the pelvic cavity. Bleeding vessels were tied with catgut, the wound was closed by silk sutures, and a Lister dressing applied. One week after the operation the stitches were removed, and the wound was found in good condition. The dressings were renewed, and on the twelfth day discontinued. Her progress was steady, and she was sitting up twenty-five days after the operation. In two weeks more she returned to her home well.

It should be stated that both cases of ovariectomy were performed in rooms engaged for that purpose, outside the hospital grounds.

NOTES ON FOUR CASES OF CEREBRO-SPINAL MENINGITIS.

BY F. C. CLARK, M. D., PROVIDENCE, R. I.

CASE I. On the evening of February 15, 1873, I was called hastily to attend a girl fourteen years of age, who had complained for a few days of feeling unwell. She had just commenced to menstruate, and it was attributed to that. Just previous to my arrival she had a strong convulsion. I was told, and fell from the bed, lost consciousness, and expired. There were no bruises upon her person, and no epileptic history. The head had been observed to be thrown back.

Several reasons made me regard cerebro-spinal meningitis as the probable cause of death. The disease was then prevailing to some extent in the city; the drainage, ventilation, and condition of the house in every way favored such a disease; the suddenness of the attack, with no previous sickness to speak of, and the convulsion.

CASE II. In the spring of 1873 I was called to see a boy with cerebro-spinal fever. He was living in poor circumstances and under adverse conditions as to food and shelter. When I saw him he was in convulsions, and it took two men to hold him. He would at times double himself up like a bow, and then straighten himself with great violence. He was taken to the Rhode Island Hospital, and treated with hydrate of chloral and bromide of potassium. He died in a day or two.

CASE III. D. E. was a boy about seventeen. He worked in the culinary department of a hotel fronting the canal. He was taken suddenly about noon, May 30, 1873. I found him in strong convulsions, prostrate upon the floor. I prescribed the usual remedies, chloral and potassium bromide, and sent him to his home in East Providence, about two miles away. The case went out of my hands, but I heard that he ultimately recovered.

CASE IV. I. G. colored, aged twelve, lived close to the canal, into which drains and vaults discharged their contents. From the whole place emanated foul, disgusting, and unhealthy odors.

About two weeks previous (March 8, 1873), his mother said, he had rheumatism, swelling and pain in the knees. The head too at the time seemed thrown back upon the shoulders, and he had nose-bleed at night once or twice. She noticed this more particularly, since he was not subject to nose-bleed. These symptoms entirely passed off. On Friday (March 21, 1873) he felt indisposed, with headache and a "nervous attack," as the mother called it. On Saturday morning (22d) he was seized with vomiting, had two chills, followed by two convulsions, during which he cried out; his head was thrown back, and the muscles of the whole body were extremely rigid. On regaining consciousness he complained of being very cold. His mother administered some physic, put hot flannels over his abdomen, and bathed his feet in warm water. In the afternoon of the same day he had acute headache in the frontal region, dizziness, and great delirium; he often cried out aloud, talking to himself or muttering. March 22d, at seven o'clock, p. m., I saw him for the first time, and he presented the following symptoms: great delirium and excitability, yet at times he would answer when spoken to; great thirst; eyes natural; countenance not so intelligent as in health; temperature not elevated; tongue slightly coated; pulse 120. I prescribed for the night bromide of potassium.

March 23d, eleven a. m. Patient passed a restless night; delirium continues; photophobia, soreness of nape of neck, headache, pain in left side; other symptoms as yesterday. Pulse 118; temperature 100° F. 6.30 p. m. No change for the better; urine dark brown and copious; pulse 128; temperature not taken.

℞ *Liquoris ammonii acetatis* ʒiij.
Spiritus aetheris nitrosi ʒi.
 Potassi iodidi ʒi. M.

Gave a teaspoonful every three hours, and continued the bromide of potassium as before.

March 24th. Passed a better night. Conjunctivæ injected, and less photophobia; hyperæsthesia; soreness of abdomen, and pain along the spine; less delirium;

some food taken during the night. Pulse 128; temperature 103.5° F.; respirations 40, and sighing, sharp, and rapid; tongue better. 6.30 p. m. Little change; less hyperæsthesia; acid drinks very grateful.

March 25th. Weakness; patient sinks down in bed; sleeplessness and restlessness; gave morphine sulphate in one-tenth to one-eighth grain doses; pulse soft and quick, 124; temperature 103°; respiration 44°; brandy or whisky and farinaceous food every two or three hours; the bromide of potassium was discontinued. 6.30 p. m. The boy slept about one hour and a half; he was in a profuse perspiration; pulse the same as in morning, but harder; temperature 102°; respiration down to 28.

March 26th. Symptoms remained the same; tongue furred. He had during the night two profuse attacks of epistaxis; slight cough; pain in side (right). Pulse soft, 112; temperature 103° F.; respirations 28. Eight p. m. Same symptoms continued. He had nose-bleed twice, but it was easily stopped. Pulse 115; temperature 102° F.; respirations 28.

March 27th. Slept well during the preceding night; one attack of nose-bleed, but quickly stopped by the application of cold water; one slimy discharge from bowels. He takes nourishment with great difficulty. Pulse 118; temperature 102° F.; respirations 28. Gave tincture of aconite root in one-drop doses every hour to bring down the pulse. (End of first week.)

March 28th. Râles are now heard in right side of chest, and a trifling dullness on percussion; cough and a little bloody expectoration. Other symptoms the same. Pulse now 100; temperature was not taken; respirations 28.

March 30th. The symptoms remain the same. The patient reported low, and little hope of recovery. Pulse 110; muscles in the nape of the neck stiff.

March 31st. Some improvement. Opisthotonos present, though more apparent when patient rises up in bed. This was never so noticeable until to-day. He desires certain kinds of food. Morphia given instead of chloral. Nose-bleed returned, but easily stopped; pulse 96.

April 1st. Eyelids seem to-day somewhat swollen; chest symptoms disappearing; abdomen tumid, but not tender; detected a gurgling in right iliac region. Pulse 96. Directed poultice to nape of neck.

April 3d. Symptoms much the same. A little sore throat, and difficulty in swallowing. Pulse 88 to 96; respiration normal; temperature 101.2° F. The aconite was now discontinued and the tincture of perchloride of iron given in three-drop doses.

April 6th. Symptoms better; nourishment more easily taken; slept better; respiration natural; pulse 96; temperature 100° to 102° F.

April 7th. Great prostration returned; profuse sweating. Patient answers well, but with difficulty. Food taken in large quantities. Pulse, etc., same.

April 14th. During ten days evident improvement was manifest, the opisthotonos disappearing; less whiskey and more food used. On the 10th relieved constipation by a dose of calomel, followed six hours afterward by sulphate of magnesium. Urine of a brick-red color. Swelling of the face was noticed the 12th, but disappeared the next day. Gave another purge, and a teaspoonful every three hours of the following:—

℞ *Liquoris ammonii acetatis* ʒiv.
 Potassi iodidi ʒiiss. M.

Milk, whisky, and beef tea have been taken often. Pulse 96.

April 30th. Continued improvement. Bowels opened four times on the 15th. Morphine not required so often. Gave one grain of sulphate of quinine in solution three times a day. Opisthotonos, however, is evidently increasing, but swelling of face disappears again. On the 17th food rejected, on account of weakness of stomach. The next day he had a sudden attack of vomiting and purging. Gave bismuth subnitrate. From that day onward convalescence was established.

The first stage in the disease in this case may be said to end on the ninth day, March 30th. After this day the temperature rarely rose above 101.7° F., and the pulse was not higher than 96 strokes a minute. The second stage, which is longer, then began, and ended the twenty-fourth day, the pulse remaining nearly stationary at 96, and the temperature at 101° F. In the first stage the pulse was nearly always between 115 and 120, temperature 102+° F. The third stage does not show so marked curves. The first stage continued nine days, the second fifteen, and the last about a week.

It will be very clearly seen that the treatment rested almost entirely upon alimentation. Drugs were used simply for symptoms which now and then had to be combated. The expectant method, then, was the one here employed. Whisky and other alcoholic liquids were not often given alone, and if so only so long as the patient could not readily take nourishment proper of any kind. All alimentation was of a liquid character for a period of three weeks. Further, a strict observance of the laws of hygiene was insisted upon; and the family moved from that locality to a better one as soon as the boy recovered. The pulse ran up as high as 128, and never fell below 100, for the first week. The temperature was 105.5° F. at its highest point, and so far as the temperature was observed for three weeks never, with but two exceptions, fell below 100° F. Symptoms of pneumonia showed themselves, and also those of typhoid fever. Oedema of the face and abdomen occurred several times; dilatation of the pupils of the eyes was noticed only in the last stage of the disease. At the termination of the disease the boy seemed to possess all his faculties intact.

Comments. It will be seen that all these cases occurred during the same year (1873), and the first half of that year. In the registration report for 1873 Dr. Snow gives thirty-nine (39) fatal cases of cerebro-spinal meningitis; and in the report for Rhode Island for the same year Dr. Caswell mentions sixty-two (62), the majority of deaths by that disease taking place during the first half of the year. Never before nor since have there been in Providence so many fatal cases. Dr. Snow, in his report for 1874, says in regard to the disease (there were only ten (10) deaths in the city in 1874 by that epidemic) that the first death was reported in 1864, and no more than one or two up to 1871, when there were 12; in 1872, ten; in 1873, the greatest number occurred. To give a little summary of the cases from Dr. Snow's reports:—

1864	1 death.
1865	2 deaths.
1866	1 death.
1867	0 deaths.
1868	1 death.
1869	0 death.
1870	0 death.
1871	12 deaths.

1872	10 deaths.
1873	39 deaths.
1874	10 deaths.
1875	6 deaths.
1876	4 deaths.
1877	7 deaths.

More than fifty per cent. of these were children under fifteen years of age. On the addition of the tenth ward the increase in the number of deaths by this disease was not sufficient to make any perceptible difference in the whole number.

The exciting causes are unknown. Proximity to the canal and cove may seem to be in some degree responsible in my own cases. But it is not known in what wards the greatest number of deaths by this disease occurred. Since the date of these cases the cove has been drained, and the general sanitary condition of the city greatly improved by the removal of vaults and wells rendered impure from the near neighborhood of privies and cess-pools, by the introduction of city water, and by the connection of houses with the sewers.

Reports of Societies.

THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

LITHOLAPAXY.

E. G. CUTLER, M. D., SECRETARY.

NOVEMBER 24, 1879. — Dr. H. J. BIGELOW addressed the society on the subject of Litholapaxy, exhibiting the latest instruments and a new evacuator.¹

The discussion was opened by Dr. FIFIELD, who said that the succession of events which lead Dr. Bigelow to the discovery of the operation was remarkable and interesting. Heurteloup forty-five years ago established the fact of the tolerance of instruments by the bladder. He also established another fact, which was the ill effects of the fragments on the bladder, and insisted on the removal of all angular pieces to make the operation safer and bring speedy relief. Cornay's instruments, as shown by the plates, in his essay, *De la Lithérétie ou Extraction des Concrétions urinaires*, published in 1845, seem almost to have served as the models of Dr. Bigelow's instruments. He first used curved, then straight, tubes. The principle of aspiration he also undertook, but the instruments were probably not well made at that period. As he lived in Rochefort, a small place, perhaps it is not surprising that he obtained no followers. Mercier originally used a balloon, which bears a very close resemblance to that of Dr. Bigelow; instead of the glass on a stand, however, he used a large valv. If so long ago the importance of size, straight tubes, aspirators, and so forth were made out, why were they not used? Probably because they were not found to be applicable in all cases. To introduce the large instruments of Dr. Bigelow one requires large-sized urethra. Otis's rule is ten times the circumference of the penis, in inches, for the size of the catheter, French scale.

The operation cannot be universally applicable if certain conditions of the neck of the bladder and prostate will not admit of the introduction of Dr. Bigelow's instruments; and if only the most fitting cases can be taken the results must necessarily be good.

Dr. T. B. CURTIS, being called upon by the chairman, said that as the testimony of others besides the

¹ See page 30 of this number.

originator of a new procedure was often of value he would communicate briefly to the society some of the results of his experience. Since the publication of Dr. Bigelow's views, Dr. Curtis had applied the new method in a number of cases with uniform success. He believed that rapid lithotomy, or litholapaxy, was destined to supersede completely the old dilatory lithotomy in multiple short sittings, and that this new method would not only prove to be applicable to all cases of vesical calculus, except those in which lithotomy was called for, but that it would also invade the present domain of lithotomy itself. It had been asserted, both in Europe and in this country, that urethra sufficiently capacious to admit the large tubes advocated by Dr. Bigelow were exceptional, and that in a considerable proportion of cases the new method would be found inapplicable. This had not proved to be the case. Dr. F. N. Otis, whose researches were made with another end in view, had found that the average calibre of the male urethra was nearly 33 French. The meatus was almost always smaller, measuring on an average 24.7. Therefore, after division of the meatus, the average urethra would admit Dr. Bigelow's largest tube, the calibre of which is 31. Moreover, it should be borne in mind that a contraction of the canal preventing the use of an efficient tube, measuring from 28 to 31, would also be a source of difficulties and dangers in the old lithotomy, with spontaneous discharge of the fragments, and would constitute a counterindication to that operation.

Dr. Curtis had used in all his cases a comparatively simple apparatus, improvised by modifying, according to Dr. Bigelow's principles, a Clover's aspirator, which had been purchased several years before in London, and which had proved quite useless in its original condition. A set of large tubes with short curves and wide eyes had been substituted for the utterly inefficient tubes provided by the maker, Weiss. A strong rubber bulb was fitted in in place of the weak one originally belonging to the instrument. Lastly, a piece of rubber tubing, a few inches long, was interposed between the catheter and the glass trap of the washing bottle. Using this instrument for the first time nearly three years ago, Dr. Curtis succeeded in removing a uric calculus weighing over a half an ounce (253 grains) in less than an hour and a half. The urine, carefully strained for a week, yielded only two and one half grains of gravel. The patient made a very rapid recovery, and has remained free from symptoms of calculus up to this date. In several cases this aspirator was used with tubes 27 and 29, without ether, for the removal of crushed fragments and entire stones small enough to be withdrawn.

One point remained on which Dr. Curtis wished to add a few remarks. The length of the operation, as performed in this country, had been criticised, and attempts had been made to improve upon Dr. Bigelow's procedure by shortening its duration. This had been effected in two ways: in the first place, by operating in a hurry, "against time," as the phrase is, with two lithotrites alternately brought out packed, and with an assistant at work cleaning them; and, in the second place, by omitting the final exploration by which the completion of the evacuation is carefully verified. Sir H. Thompson has expressly stated that he prefers to postpone the search for lost fragments, at the risk of leaving the evacuation uncompleted, rather than protract the operation, as he thinks, needlessly. The cases

recently published by him illustrate this practice. His largest stone, weighing 521 grains, was thus dealt with in two successive operations. This proceeding, however, is a relic of the old traditions, and is unavoidably attended, in a certain measure, by the dangers which it is the object of Dr. Bigelow's method to avoid. With etherization there need be no undue haste to terminate the operation. On the other hand, a small fragment left behind may produce the most disastrous results. A case lately treated by Dr. Curtis illustrates the dangers which are thus likely to be incurred. An aged patient, with multiple small calculi, was operated upon by Dr. Bigelow's method. After about three quarters of an hour of crushing and aspiration, the bladder seemed to be relieved of all fragments. As the patient had a fairly large, unobstructed urethra, Dr. Curtis, influenced by the then recently published recommendations of Sir H. Thompson, refrained from the usual prolonged exploration, and concluded the operation. The immediate effects were soon recovered from, and on the third day the patient was up and dressed. He continued, however, to suffer from frequent painful micturition, with purulent urine.

A second exploration under ether was found necessary, which resulted in the detection and removal of a small last fragment, less than a third of an inch in diameter. This second operation was followed by a severe febrile and inflammatory reaction (with a temperature of 105°, great suffering and delirium), which threatened to carry off the patient, and from which he is now convalescing. Judging by the results attained in this case, as compared with his other cases in which complete evacuation was effected and verified by a prolonged leisurely operation, and taking into consideration the theory upon which the procedure is based, Dr. Curtis firmly believed that it was in all cases preferable to protract the operation for two hours or more, if necessary, rather than incur the risk of leaving fragments in the bladder.

Recent Literature.

Outlines of the Practice of Medicine, with Special Reference to the Prognosis and Treatment of Disease.

With appropriate Formulæ and Illustrations. By SAMUEL FENWICK, M. D., Lecturer on the Principles and Practice of Medicine at the London Hospital. Philadelphia: Lindsay and Blakiston. 1880.

Dr. Fenwick states that he gives this small volume, having its origin in previously delivered lectures, to the public with a view to combat a tendency, existing especially among students and young practitioners, to adopt physical diagnosis as the basis for treatment to the neglect of those indications furnished by symptoms, which are of so much importance in leading to a correct method of rational treatment. The book is, in a word, a protest against routine practice. The prognosis and treatment of the more usual diseases of the various organs and of the abnormal conditions of the general system are outlined as fully as the space occupied will permit. It is an eminently practical little treatise, pervaded with much common sense, and would doubtless be found useful, particularly by advanced students. The appended formulæ are collected from various sources.

Medical and Surgical Journal.

THURSDAY, JANUARY 8, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Osgood and Company, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to
HOUGHTON, OSGOOD AND COMPANY, BOSTON, MASS.

CODES OF ETHICS.

THE councilors for the Massachusetts Medical Society appointed a committee some six months since to draw up a code of ethics for the government of the Fellows of the society. The subject, we believe, had been under consideration previously to the appointment of this final committee. We have been favored with the perusal of the printed drafts of two codes: the one, which is by far the longer and fuller, signed by four members; the other, much more concise and avoiding details, signed by one member. These two drafts are to be submitted to a meeting of the councilors early in February, and we suppose, as the matter has been already so long under discussion, the probabilities are that one or the other of these drafts, without any very essential modifications, will be recommended to the society for its adoption. It is not our wish to anticipate the decision of the councilors of the Massachusetts Medical Society, but the subject is evidently attracting the attention of many of our readers, and will presently be brought more prominently before them.

The letters of the practitioner of Pine Ridge are still fresh, and we publish in our present issue a communication from a correspondent at Worcester, accompanied by a code which he thinks good in theory and in practice.

A few reflections therefore naturally arise in regard to codes in general, and forms of codes in particular, which, though throwing but little light themselves, may call forth illuminating opinions from others.

It would be generally conceded that a code of ethics for the government of any body of men in their relations to each other and to the outside world is requisite only in so far as there may be among their number the ignorant or the evil-minded. The ignorant are unaware of the obligations incurred by associating themselves with others; the evil-minded, knowing these obligations, seek to evade them. And then there is that disturbing element of "human nature" which, without adopting the dogma of original sin, we are forced to acknowledge still clings to a man even after he has developed into "an educated gentleman" and a member of the Massachusetts Medical Society; its misdeeds, however, we must class with those of the evil-minded.

Taking this general view of the situation, the questions which any society or association has to ask itself are these: How numerous among its members are the ignorant or the evil-minded; how frequent their short-

comings, or flagrant their transgressions? Can a code of ethics instruct the former, and will it restrain the latter? If so, what form of code will accomplish these objects the most simply and the most thoroughly? We have not unfrequently heard it said that a code is, as a rule, more particularly desired by and desirable among practitioners in the country; this may be true, and yet we should be loath to believe that there was more ignorance of the fundamental rules of the courtesies of life, more evil intent, more human nature, in the country than in the city. We are led to suppose, however, that this may be the case when the man in the country cries for a code, and the man in the city protests that he is insulted if you offer him one. It may therefore be thought best to try to gratify the longings and possibly necessities of one portion of the medical fraternity at the expense of the delicate sensibilities of another portion. The question then arises, Can it be done? Can a code of ethics give the instincts of a gentleman to one who has them not; can it enlighten one who, knowing the golden rule, is incompetent to apply it in the practice of medicine? And, secondly, can such penalties be attached to its violation — can and will these penalties be so enforced — as to restrain the evil-minded? This question of the feasibility of accomplishing the objects for which a code might be demanded we will not attempt to decide. We know there are those who are disposed to think that the weaknesses of our mortal nature may find comfort in arbitration, and that the vigorously depraved will always find an escape through any paper barrier.

Joining ourselves, however, for the moment, with those who think that a code of ethics is required for regularly educated practitioners of medicine, and that some form of code will secure all, or much, that is desired, the final question presents itself as to what that form shall be; and this immediately leads us to ask ourselves what we expect from a code of medical ethics. To this a fair reply would be, Simplicity and thoroughness in teaching physicians how to practice medicine, — which the best and wisest men for centuries have agreed should not be regarded as a trade, and yet by which its followers must earn their bread, — with the greatest benefit to the community at large and the least friction among themselves. The old problem in mechanics of unlimited power and no friction suggests scarcely greater difficulties. If the code is too short, it consists almost necessarily of beautiful platitudes, and we can see no reason for going beyond the "do unto others as you would be done by;" if too long, it falls to the ground from its own weight; if there is no detail, the ignorant will not be instructed, nor will the evil-minded be hedged in; if there is too much detail, the enlightened and sensitive will not submit, nor can their rebellious conduct be easily reached. Will a code of ethics restrain the social tendencies of a physician's wife, or bring him to punishment for them? And what will it effect with the aged senior consultant, who vows he will give his opinion first instead of last, or *vice versa*? We will not involve ourselves in the perplexities which beset us in regard to this final question of form.

If there is to be a code, it would seem a pity that all the States should not have one in common, and we have no doubt that the laity would heartily concur in this sentiment.

We believe that of the American Medical Association has been adopted by very many States, which is a strong, we will not say the only, argument in its favor. If it were thought generally best to adopt a code of ethics of that length, we could wish it evinced the careful thought, the extended research, and the elegant diction of the draft-code prepared for submission to the councilors of the Massachusetts Medical Society as a majority report of their committee.

MEDICAL NOTES.

— Col. Geo. E. Waring has been telegraphed for to go to Memphis with reference to the proposed new system of drainage. This looks like real work.

— The twenty-eighth annual session of the Iowa State Medical Society will be held in Des Moines, beginning Tuesday, January 27th, and continuing three days. The following papers have been promised: Quinine as an Anti-Congestive Remedy, J. M. Knott, M. D., Sioux City. Dressing of Wounds, J. M. Emmert, M. D., Atlantic. Ovariectomy, a Case of, G. R. Skinner, M. D., Cedar Rapids. Consumption, a Nerve Disease, J. J. M. Angear, Ft. Madison. Ozone Observations at Iowa City, Gustavus Hinrichs, M. D., Iowa City. Insanity during Pregnancy, W. C. Schultze, M. D., Marengo. Causes and Treatment of Inflammation of Joints, W. W. Grant, M. D., Davenport. Pyrexia as an Element of the Typhoid Condition, D. Scofield, M. D., Washington. Criminal Abortion, H. H. Maynard, M. D., Tipton. The Metric System in Medicine, John North, M. D., Keokuk. Special Surgery in Incised Wounds, W. F. Peck, M. D., Davenport. Ovarian Hysteria, W. H. Gibson, M. D., Clariton. A New Method of Arresting Puerperal Eclampsia, G. M. Staples, M. D., Dubuque. Treatment of Strictures of the Nasal Duct, C. M. Hobby, M. D., Iowa City. Ovariectomy by Enucleation, with Remarks on the Value of Antiseptics in the After-Treatment, J. Williamson, M. D., Ottumwa. Anaesthetics in Obstetrical Practice, H. L. Getz, M. D., Marshalltown. Cerebral Haemorrhage, A. Reynolds, M. D., Independence. Scarlatina, H. M. Dean, M. D., Muscatine. Some of the New Ideas of the Nervous System, W. D. Middleton, M. D., Davenport. The coming session will be one of more than ordinary interest. In addition to the professional papers action will be taken relative to several changes in the constitution and by-laws, and reports will be presented relative to the establishment of a State Board of Health and the regulation of the practice of medicine within the State. A large attendance is expected. Officers: president, G. P. Hanawalt, M. D., Des Moines; first vice-president, N. W. McClure, M. D., Mt. Pleasant; second vice-president, D. Scofield, M. D., Washington; secretary, J. F. Kennedy, M. D., Des Moines; assistant secretary, Geo. W. Tibbits, M. D., Des Moines; treasurer, G. R. Skinner, M. D., Cedar Rapids.

— The *British Medical Journal* gives the following well-merited eulogy to the Scotch ovariectomist, entitled *A Great Deed in Surgery*:—

“The *Scottsman* of November 20th contains a just and faithful tribute to the great services of Dr. Thomas Keith, whose grand successes in ovariectomy have been the admiration of the surgical world, and whose work has been carried on with a modesty, an anxious care, and a brilliant result such as have deserved this public recognition. As a rule, any such notice in public papers is to be deprecated. In this instance, however, the singular services rendered to mankind by Keith and Spencer Wells are such as to afford reason for satisfaction that the great organs of public opinion should take a suitable opportunity for expressing the public gratitude to rare benefactors of their race, and to the labors of both ample and discriminating justice is done in this excellent article. We would willingly quote it entire, for it is accurate, discriminating, and truthful. Dr. Keith has performed ovariectomy seventy times in succession without a death, and the operation has, in his hands and those of Spencer Wells, become less fatal than amputations of the leg or arm, though it involves the removal from the abdominal cavity of tumors which vary in weight from ten to one hundred pounds. The article says truly that

“Five and thirty years ago, and less, this operation — now so safe — was derided and denounced by the medical profession, and those who performed it were called dangerous men and murderers. Even the sagacious Syme, when writing of the operation in 1837, says that, “though one or two fortunate patients may have escaped, after being freed from part or even the whole of the disease, it would be very unjustifiable to repeat such dangerous experiments, since it is evident that for every life prolonged by them many must be sacrificed.” Syme never performed the operation himself, but he lived to change his opinion, and to acknowledge the triumphs of Thomas Keith.”

“After giving a brief history of the origin of ovariectomy in the hands of McDowell, Clay, Lizars, and Washington Atlee, it continues as follows:—

“It was not till after 1858 that ovariectomy began to be accepted as one of the legitimate operations in surgery. So late as 1850, Mr. Lawrence, perhaps the greatest surgeon of his day, asked whether it could be encouraged or continued without danger to the character of the profession, and it was alleged by a distinguished reviewer that a fundamental principle of medical morality was outraged when an operation, so fearful in its nature and often so immediately fatal in its results, was performed. It was in the year referred to, namely, 1858, that Mr. Spencer Wells, of London, began to operate, and since that time he has performed the operation nearly one thousand times, with most gratifying results. Four years later, in 1862, Dr. Thomas Keith performed his first operation, and down to the present date he has operated upwards of three hundred times, Dr. James Sidey having been usually his chief assistant. These two men, Spencer Wells and Thomas Keith, are now the fore-

most ovariologists in the world. They are not rivals, but fast friends, who have taken lessons from each other. A very remarkable success has attended Mr. Wells, but a success still more remarkable has fallen to Dr. Keith. In the practice of both of them fatal results—never so high as with other surgeons—have steadily diminished. From the outset, however, Dr. Keith took the first place, and he has done more than keep it. He now shows results which have never been approached, for it appears that of his last hundred operations only three have ended fatally, while of his last seventy not one has ended fatally. In attaining these wonderful results, both Keith and Wells have lately been aided by the employment of antiseptics, as recommended by Lister, whose niche in the temple of fame will be one *on the line*. Something, perhaps, is also due to those aids in diagnosis by which malignancy in these tumors is more certainly disclosed, and with the discovery of which the name of Dr. Foulis, of Edinburgh, has acquired great distinction. It is possible, too, that one cause of the great success of these two operators is revealed by Dr. Keith when he says: "No one knows the anxiety that ovariectomy has given me, nor the time and thought and care I have bestowed on the patients." It is not true that all are ignorant of this, though Dr. Keith may think so, for it is well known to some that a devoted attention to their patients, involving great self-sacrifice, has characterized both him and Mr. Wells. To secure favorable conditions, Keith established a little hospital, at his own charge, and not far from his own residence; and many a poor woman has received in it an unceasing attention from himself and his trained nurses, without any expectation of payment. No doubt he has had wealthy patients, and has been summoned to Italy and other distant countries to operate, but nearly all his care and time have been generously expended on the very poor, who could only pay him with gratitude."

—The bill authorizing the city of Memphis to levy a direct two per cent. tax for carrying out the sanitary improvements recommended by the committee appointed by the National Board of Health passed the Tennessee legislature on the 23d ult., and at once received the governor's signature. In the mean time, an enormous list of nuisances has been sent to the health officer of Memphis for abatement by the inspectors of the National Board and others, which alone would tax all the resources of the ablest sanitarians. The better sanitation demanded by the whole country applies as well to skillful direction of the daily work of preserving cleanliness as to inaugurating great reforms in the methods of disposing of filth, and if the ill-fated city does not secure such skilled direction of the efforts in that direction the good results hoped for certainly will not follow.

PROVIDENCE.

—The sixteenth annual report of the Rhode Island Hospital, which has just appeared, shows a very satisfactory condition of that institution. The total number of patients treated during the year was 469,

of whom 188 were in the medical, 230 in the surgical, and 51 in the ophthalmic wards. In the out-patient departments the whole number who received treatment was 4237. The total income for the year was \$21,895.41, the total expenses \$24,062.81, showing the institution to be nearly self-supporting. The deficiency of \$2167.40 is generously met by guarantors to the number of one hundred. There are forty permanent and eight annual free beds, so that no suitable case need be refused admission. The hospital is doing a good work, but is hampered in its management and limited in its sphere of usefulness by lack of funds. This obstacle will, however, be removed by time, as the endowment fund is continually increasing, and every year shows the institution to be more nearly self-supporting.

—Upon recommendation of the superintendent of health, the following regulations have been adopted by the board of aldermen:—

(1.) Every physician having knowledge of the existence of any case of contagious, infectious, or epidemic diseases within the city of Providence shall immediately remit a report thereof in writing to the superintendent of health of said city, with such particulars as the said superintendent may indicate on blanks furnished for that purpose.

(2.) The diseases referred to in the preceding section shall, among others, include especially small-pox, diphtheria, typhoid fever, typhus fever, scarlet fever, or scarlatina, cerebro-spinal meningitis or spotted fever, measles, and whooping-cough.

(3.) Any physician who shall fail to comply with the preceding rules and regulations shall be fined not less than two nor more than ten dollars for each day of such neglect, after having knowledge thereof as aforesaid.

NEW YORK.

—December 27th and 28th were "Hospital Saturday and Sunday" in New York, and this was the first time that such days have been generally observed in the city, in imitation of the kindly custom of setting apart one Sunday in the year for the benefit of the hospitals, through alms and donations, which has long been maintained in London. In New York the idea was first taken up in the autumn of 1874, at the annual meeting of the board of managers of St. Luke's Hospital, who afterwards made an appeal to the various Episcopal churches of the city for a collection to be made on the last Sunday in December. Bishop Potter at once indorsed the appeal in a letter to the clergy, and the pecuniary result was so satisfactory that similar collections have been repeated every year. Since 1877 St. Mary's Free Hospital for children has also shared the benefit of the offerings thus made.

At the meeting of the managers of St. Luke's, in November, 1878, the superintendent of the hospital read a paper showing that till 1849 the care of the sick poor was left entirely to the Bellevue and New York hospitals. In that year the Rev. Dr. Muhlenberg made his first appeal for the foundation of a Church hospital, and the result was the establishment of St. Luke's, in 1850. About the same time St. Vin-

cent's Hospital was established by the Roman Catholics, and in 1852 Mount Sinai Hospital by the Hebrews; while the Presbyterian Hospital was founded in 1868. These, with the Roosevelt, the German, and other private hospitals, about twenty in number, accommodated more than eighteen hundred patients, and annually treated some twenty thousand; each one opening its doors to the poor of every nationality and sect.

The paper ended with a recommendation that the Hospital Sunday Committee should be empowered to address a circular letter proposing a general Hospital Sunday to the representatives of other religious bodies. In December a conference was held between the managers of St. Luke's and a number of prominent Episcopalians, both clergymen and laymen, and a committee of five was then appointed to invite such of the hospital associations of the city as they might deem it wise to select, to confer as to the wisdom and expediency of inaugurating a general hospital day.

This conference was held at St. Luke's Hospital, on the 7th of January, 1879, and was attended by official representatives of thirteen hospitals, as well as by a number of prominent clergymen and other invited guests. A committee was appointed to arrange the details of the matter, and the movement has proved a most successful one. In all the stations of the elevated railroads and all the post-office stations, as well as in other public places, boxes were placed for receiving contributions; over each there being a yellow flag with the inscription, "Hospital Saturday," in black letters upon it. Yellow flags were also to be seen upon many of the street cars and omnibuses. On Saturday, the 27th, collections were taken up in all the Jewish synagogues, and on Sunday, the 28th, in all the churches of the various Protestant denominations. In addition, contributions were received by the general treasurer of the fund, and by gentlemen prominent in business circles, who represented the chamber of commerce, the stock exchange, the cotton exchange, the produce exchange, the maritime exchange, the fire and marine underwriters, and the banks and bankers, respectively. One of the largest checks sent in was that of Mr. William H. Vanderbilt for \$1000. Donors who preferred to make their gifts for any particular institution had the privilege of so doing; while all contributions not thus designated are to be divided under an equitable plan, based upon the charity work and the needs of each, among the various hospitals uniting in the movement. The committee to make the distribution consists of Mayor Cooper, Postmaster James, William E. Dodge, Jr., George H. Andrews, Jesse Seligman, and John W. Harper.

— The Flower and Fruit Mission, as previously announced, decorated all the hospitals for Christmas with evergreens and appropriate wall mottoes; and, beside, distributed large quantities of white grapes, oranges, and other delicacies among the sick poor, not only in the hospitals, but also in many tenement houses.

— Dr. William A. Hammond has brought suit

against Dr. Allan McLane Hamilton in the United States Court for an alleged infringement of copyright. He claims that Dr. Hamilton's book on diseases of the nervous system was "pirated" from his own, and asks that its publication be prohibited, and the profits from its sale thus far be turned over to him.

— The boy, at Paterson, New Jersey, whose brain was cut into by a circular saw lived for nearly an entire week after the accident. He was conscious the greater part of the time, and remained so up to the last; but on the eighth day from the receipt of the injury he was seized with convulsions, which caused death by exhaustion. The parents refused to allow an autopsy to be made.

— Measles is at present epidemic in New York. The disease is mostly of rather a mild type, but is prevailing in a malignant form at the Baby Shelter in West Twentieth Street, where one fourth of the twenty infants in the institution have already died of it. Generally it is very evenly distributed from the Battery to the Harlem River, no particular locality being specially affected.

— A large public meeting was held at Cooper Institute, on the 18th of December, to consider the evils existing in the manner in which the insane are at present cared for. Addresses were delivered by George William Curtis, who presided, the Rev. Drs. H. W. Bellows and R. H. Storrs, and Dr. E. C. Seguin, and letters were read from Dr. Willard Parker and others. Among the resolutions adopted were the following: That a lunacy commission, modeled to a certain extent after those which have proved successful in Great Britain and elsewhere, should be appointed in the State of New York, the duties of such commission to be, permanently to supervise insane asylums, both public and private, to attend to complaints and controversies, and to raise the standard of scientific study and treatment of the insane; that a committee should be appointed by the chairman of the meeting to devise a plan for the organization of such a lunacy commission; and that the meeting also recommended the organization of a national association for the protection of the insane, the above committee being instructed to take the necessary steps for the formation of such an association. There was considerable feeling in regard to this meeting on the part of a number of prominent medical men and others, on account of the manner in which it was gotten up and conducted; and hence they refused to give it their countenance.

— The body of Mr. Charles A. McCrury, the son of one of the leading dry goods dealers in this city, was recently incinerated in the crematory erected by the late Dr. Le Moyné, in Washington, Pa. He was strongly opposed to the ordinary methods of burial, and left a written request to his parents that his body should be burned. The cremation was performed under the direction of the brother of the deceased and a Presbyterian clergyman; and when it was completed the ashes were found to weigh only about five pounds.

PHILADELPHIA.

—The board of managers of the Pennsylvania Hospital having made a liberal appropriation in aid of the project, Drs. Morton and Hunt of the surgical staff are now actively engaged in preparing a handsome octavo volume to be entitled *Surgery in the Pennsylvania Hospital*, which it is expected will not only contain valuable statistics of operations performed in the institution (which has been in existence now for nearly one hundred and thirty years), but will also reflect as nearly as possible the prevailing methods of practice that are now in use in the wards of this, which is preëminently a recent accident hospital.

—The students in attendance upon the Jefferson Medical College have demonstrated their regard and high esteem for their late teacher of physiology, Professor James Aitken Meigs, recently deceased, by presenting his life-size portrait in oil, handsomely framed, to the trustees and faculty of the college. This testimonial was a spontaneous expression from the class, the presentation speech being made by one of their number, Dr. H. B. Lowry, of Proctor, West Virginia. The occasion selected was after Professor DaCosta's lecture, on Friday, December 12, 1879. The painting was received on behalf of the college by Dr. E. B. Gardette, the president of the board of trustees. It will be hung in the amphitheatre of the new hospital, which is already adorned by a marble bust of Dr. George McClelland, the founder of the school, and with the portraits of Professors Joseph Pancoast and Samuel D. Gross, which were lately presented to the institution by the Alumni Association of the college.

CHICAGO.

—Scarlet fever has visited a part of this city of late in an epidemic form. Curiously it has been partially circumscribed—that is, the epidemic—to some parts of the city in the North Division, where the ground is sandy, the surface high, the streets and sewers in good condition. So far nobody knows the cause of the epidemic. Two meetings of citizens residing in this section have been held to discover, if possible, the cause of the visitation and a remedy. These meetings have strongly censured the management of the public school, and have attempted to fasten the blame for the epidemic upon one school in particular, occupying an unsanitary building, and from which it appears a few cases have originated. But no real evidence was found or offered that would fix the responsibility for the epidemic upon this or any school. So far the cause of this, as of all epidemics of scarlet fever, is inscrutable. Unfortunately the system of posting red cards announcing the fact upon infected houses, in the hope of isolating the cases so thoroughly as to stay any spread of the disease, has not been attended with success.

—On the 24th of December the engines started and the water moved from the lake riverward by the Fullerton Avenue conduit. This enterprise and experiment has been made by the city at enormous expense, for the purpose of clearing the north branch of the river of impure water and foul emanations.

The main river and south branch have for several years been in a state of tolerable decency from the current upward, from the lake, of water flowing from the branch into the canal and on toward the Mississippi River. As many large sewers empty into the river, this current ceases for a while after heavy rains, and the whole river becomes malodorous. But the north branch has been constantly very offensive. The scheme of the conduit is to force water from the lake through this new channel along the north city limits into the river, make a stronger current downward in that sluggish stream and clear it, or to force the water in an opposite direction and clear the stream by an upward current. Opinions are widely diverse as to the effect we may look for. If more water flows down the north branch than, with what comes up the main river, the canal outlet can take care of, then a current will be made down the main channel into the lake, with possible danger to the water-supply, not to speak of the bad odors it will distribute. In any case, the current either way in the main river must be nearly abolished by the conduit delivering water into the river, while if it carry a current from the north branch into the lake a strong current will come up both the main river and this channel; but then the foul water will be emptied into the lake at Fullerton Avenue, and on this point one of the most interesting disputes is going on. One party insist that before the sewage can reach the "crib," two miles off shore at this point, which is the inlet of our city water-supply, it will become oxidized and inert. This view was shared by our late city engineer, Chesbrough. On the other hand, it is claimed that there is an undertow, a deep current off shore, that would carry the sewage to the crib, and so contaminate the water-supply. Those who hold this opinion claim, with accumulating evidence in their favor, that now when there is a down current in the main river the hydrant water is actually polluted to a slight degree in this manner.

Correspondence.

SURGICAL OPERATIONS WITHOUT LIGATURES.

MR. EDITOR, — In 1872, Mrs. —, of Kittery, Maine, aged about thirty-eight, of light, sanguine complexion, mother of two children, had a tumor of the left breast about the size of a duck's egg, which began soon after the cessation of lactation with her last child. This tumor made its appearance on the inner side of the left breast just below the nipple, which felt hard and doughy to the touch. The nipple was retracted, and there was a deep, dark areola around it. Her suffering was so great that she was unable to sleep, and it had occasioned a general loss of appetite and strength.

She was placed under the influence of ether, and the usual elliptical incisions were made. In so doing branches of the inferior mammary artery were laid bare, and traction was made upon them previous to their general division with a saw-like movement of the bistoury. Retraction of these arteries took place,

completely closing them against any hæmorrhage. Some slight hæmorrhage from smaller vessels was controlled by torsion. The parts were now brought together without the use of any ligatures. The wound was closed with five silver sutures and adhesive plaster, and healed almost entirely by first intention.

In the fall of 1878 a young girl from Attleboro', aged fifteen or sixteen, received an injury by a stone thrown against her breast, where a hard swelling arose and developed into a cystic adenocoele. The whole breast became much enlarged, swollen, and painful just above the nipple. The tumor and the hard swelling continuing to grow in spite of treatment, it was decided to amputate the breast. Being called to perform the operation, after etherization I proceeded to remove the greater portion of the breast by making semi-elliptical incisions, keeping the vessels well on the stretch. Her attending physician wrote me that the entire wound healed by the first intention, or at the primary dressing without any suppuration. This patient being young and in vigorous health, well nourished, and with breasts enormously large, the circulation was very free, and the tendency to hæmorrhage was much greater than in the first case, where continued suffering had caused a reduction in the vital forces, and at the same time enfeebled the circulation.

This operation shows the contractile power of the muscular coats of the arteries when traction is made on them before their division. To illustrate still further how much can be done in many operations without the use of ligatures by taking advantage of this contractile power of the arteries I will relate the following case:—

Mrs. H. of Concord, Mass., aged sixty-eight, on November 7, 1878, consulted me for a large fatty, bell-shaped, fibroid tumor which grew from the gluteus maximus, was suspended by a pedicle of about two and a half inches in diameter, and extended nearly to her knee on the left side. It had existed over twenty-five years, and a portion of the inferior part had sloughed obliquely off, leaving a large ulcerated surface which was discharging a very offensive fluid. The constant weight—about three pounds—had caused a prolapsus uteri, together with a partial prolapsus of the anus and bladder. This tumor, from its discharge and the burden of carrying it,—as the patient was very slight in stature,—very much weakened and enfeebled her.

On the 12th of November, after etherization, I operated on the tumor, with the assistance of Dr. E. B. Webb, of Boston, by making two longitudinal elliptical incisions as close as convenient to the pedicle, and removing all the attachments except where the arteries ramified into the substance of the tumor. These arteries were very large, and accompanied by a vein fully equal in size. Before the final division of the vessels I made retraction, placing them greatly on the stretch, and then proceeded slowly to divide them with a saw-like motion, as related above. Full contraction and closure of the arteries took place. The wound was now brought together, and coaptation effected by silver sutures and Dr. Martin's United States army adhesive plaster. It healed almost entirely from the first dressing, excepting a small portion, about three quarters of an inch of the lower part of the incision, which was designedly left open for drainage, and so kept by a few threads of coarse saddler's silk. The patient in two weeks was able to return home perfectly healed, with her prolapsed organs restored to their natural conditions, the

uterus being supported with a Hodge's hard rubber pessary. She was ordered to take quinine and iron, and when she visited me in the winter she had gained so much flesh and strength that she considered herself comparatively young again.

Neither in major nor minor operations have I had secondary hæmorrhage by this method so frequently as when I have been obliged to resort to ligatures, and I have had better success in the healing, since the parts so brought together have generally united by first intention. My attention was called to this contractility of the arteries from the fact that in early life I noticed that in many lacerated wounds we have but little hæmorrhage where we should have supposed from the size of the arteries that there would be much, and that such wounds, when proper coaptation could be had,—when freed from dust and oil,—would generally heal by first intention; but where ligatures, even though small, were used in fresh wounds, suppuration took place almost invariably.

JOSEPH H. WARREN, M. D.

MEDICAL ETHICS.

MR. EDITOR.—The puerilities of "codes of medical ethics" are very disgusting to many physicians, who are not flattered by the assumption that they do not know how to conduct themselves as gentlemen. I say this with very great respect for my excellent friends who have drawn up "codes" for the Massachusetts Medical Society, but whom I consider to be working here for no good. I send you a "code" which I drew up myself some two years ago, and designed to have sent into the meeting of the councilors, but withheld for cause. I think you will find it simple enough, and comprehensive. We practice by it here, although it has never been presented, and are happy; and Worcester is the paradise of physicians, socially. Publish it if you think it will do you any good.

Yours respectfully, JOSEPH SARGENT.
Worcester, December 31st.

CODE OF ETHICS FOR THE MASSACHUSETTS MEDICAL SOCIETY.

Assuming that membership of the Massachusetts Medical Society is conceded only to worthy persons, of good character and good education, no general code of ethics is necessary for them which is not equally recognized by all educated gentlemen.

But inasmuch as the relation of the physician to the patient and to other physicians is often a peculiar one, it may be wise to keep in mind certain other principles of special application, and which are recommended by experience and sanctioned by wisdom.

(1) The physicians should remember always that he is called for the good of the patient; and this consideration should be uppermost in his mind, prompting him to thoroughness, to faithfulness, and to diligence, without selfishness or vainglory.

(2) With the same view to the patient's good, and also having in mind the importance and the dignity of his profession, he should call counsel when in doubt, or when requested, and in cases of unusual gravity and responsibility, and should call good counsel. And the deliberations and discussions in council should be confidential.

(3) He should discourage quackery, which is false

pretense, and should make himself no partner to this by consulting with quacks, which is not only to be false himself, but to jeopardize the patient, to injure the public, and to degrade the profession.

(4.) He should not interfere with any other physician; and, especially, should not undertake to undermine his practice or his reputation. This not only injures his fellow but his fellow's patients, and also subjects his own motives to suspicion and demeans the calling.

(5.) The relation of physician and patient is strictly and wholly confidential, and neither the patient, nor the sickness, nor the surroundings, should be made the subject of general conversation.

(6.) The professional differences of physicians should be settled between themselves, the public being no competent arbiters.

(7.) The practice of medicine should be conducted not only as a liberal profession, but also as a practical philanthropy, personal and public. The sick poor should never be allowed to suffer from neglect, and public health should be looked upon always as a particular charge. And while the good physician should claim an honorable or even a generous support, mercenary motives should never restrain professional benevolence, nor prevent gratuitous service in proper charity.

MEDICAL COLLEGE DEAD-HEADISM.

MR. EDITOR, — The medical press of the country has heralded generally, with greater or less flourish of trumpets, the fact that Rush Medical School of Chicago has taken an advanced step in throwing open its lectureships to public competition. Surely that sounds well, as was doubtless intended. But what are the facts of the case? Why, an opening is offered to members of the medical profession to obtain questionable honors by a greater or less individual sacrifice; at the same time, this medical school secures both a desirable teacher and a drudge without expense to itself. The circular of the secretary gravely informs us that, "the concours for the lectureship on gynaecology in the spring course of lectures in this college will be held," etc., on a certain date. Then follows the statement that "the position is one commanding no pecuniary remuneration," but, "as a rule, the professorships in the winter faculty are filled by selections from the spring faculty. . . . The points determining the choice of a candidate for the vacancy are: first, his *ability to teach clearly, correctly, and forcefully*; second, his past record and present standing professionally; and, third, his professional attainments and general culture."

Now, Mr. Editor, is not this a case of rank dead-headism? He has the inestimable privilege of seeing his name in the annual catalogue, of knowing that he is performing labor for which others are paid, and of waiting anxiously for "dead men's shoes," with fifty chances to one of never wearing them.

It is, I believe, a generally accepted rule of the present day that "the laborer is worthy of his hire" in proportion to the amount of work done; but in the case of Rush and several other medical colleges all this is reversed. In spite of the idea conveyed that the position is open to all, such is really not the case, being practically limited to residents of Chicago or young

men of fortune; unless one is possessed of a fixed income of at least a thousand a year outside of any sum that may result from his profession, he cannot compete and wear the empty honor of a lecturer. The same amount of application and study necessary to fill this position, if bestowed upon literature, would yield some slight return, — a return that would prove most acceptable to the young struggling practitioner. He could also, to a great extent, choose his own time; but here, if his duties are performed faithfully and conscientiously, his whole time, without choice or selection, is at the disposal of the college during the term. To be sure, he may pick up a few stray dollars by means of private classes, but such are of questionable utility, either to teacher or student, and but open the door for many other errors of a grave nature.

Again, but scant, if any, reputation is obtained by the spring lecturer, all being absorbed by his winter compeer; he has all the trouble of making the ground fallow and sowing the seed, while the latter secures the harvest as a full-fledged professor. The former is continually overshadowed by the latter, through no fault, however, of either, but rather the parsimony of the institution. The lecturer is forced to remove the obstacles from the pathway of the professor, and as a reward is merely covered by the dust of the latter as he rolls by at his ease; or, if I may be allowed the simile, the one is but the running horse that follows close behind the fast and gifted trotter, to urge the latter to greater brilliancy of exertion; meantime, the poor runner, constantly chafing, and ever held in check, is hard worked, receives none of the caresses and plaudits of the gaping multitude, has no share in the purse that is won, though due largely to his individual efforts, and stands but a bare accidental chance of ever obtaining a first place.

Now I ask, Is this fair or just? The most humble and useless of literary institutions, no matter how narrow or bigoted, pay their tutors *something*. We constantly hear members of the profession grumbling because they are so illy requited for their labors, yet here is an example set the laity at the very outset by a medical institution of considerable fame, and one cannot conceive that it thereby adds to its dignity.

This is no fancy sketch, but one founded on facts. The evil decreed is the direct result of *cheap medical education*, which is the curse of the United States. Compare the number of graduates each year with the number that seek admission into our medical societies. Only one in ten appears in the latter list. Where are the other nine? Gone to swell the ranks of charlatans largely. Then, too, a goodly portion of undergraduates take upon themselves the title of doctor. Hundreds of young men seek the cheap schools each year, and, knowing their inability to stand the test of the final examination, rush off to join the band whose name is legion. This is especially true of Western colleges.

If Rush Medical College cannot afford to pay its teachers with its present fees, surely, with its standing, these might be raised until it could. This with a thorough and non-optional graded course, like that of Harvard, further fortified by a stringent examination as to literary and classical attainments for matriculation, would put it in the front rank of medical schools, and render it supreme to the rill-rall institutions that now swarm and are constantly being added to west of the Alleghanies.

I have no desire to seem captious, nor to fling at Rush Medical College in particular, for in its faculty I have both acquaintances and friends; but it has given an opportunity to exhibit an evil that is general, one

that can but disgrace any institution where it is practiced. Personally no one desires the success of Rush more than does the writer.

WOLVERINE.

December 24, 1879.

REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 27, 1879.

Cities.	Population estimated for July, 1875.	Reported Deaths in each.	Deaths under Five Years.	Percentage of total Deaths from

Two thousand two hundred and eighty-four deaths were reported; 794 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 476, consumption 335, lung diseases 301, diphtheria and croup 227, scarlet fever 81, typhoid fever 33, measles 33, whooping-cough 25, diarrheal diseases 25, malarial fevers 22, erysipelas 14, cerebro-spinal meningitis seven, small-pox three. From *measles*, New York 22, Chicago eight, Brooklyn two, St. Louis one. From *whooping-cough*, New York five, Boston four, Brooklyn and Pittsburgh three, Cleveland two, Philadelphia, Chicago, Baltimore, Cincinnati, New Haven, Worcester, Lawrence, and Lynn one. From *malarial fevers*, New York eight, Brooklyn four, St. Louis and New Orleans three, Cincinnati two, Chicago and New Haven one. From *erysipelas*, Philadelphia three, New York, Chicago, Cincinnati, and Cleveland two, Baltimore, Boston, and New Orleans one. From *cerebro-spinal meningitis*, St. Louis and Cincinnati two, New York, Pittsburgh, and Taunton one. From *small-pox*, Philadelphia, Chicago, and District of Columbia one.

There was an increased mortality from the principal "zymotic" diseases, and, in order of the increase, from diphtheria, measles, malarial fevers, whooping-cough, scarlet fever, and erysipelas. Pneumonia, too, was much more fatal; consumption and diarrheal diseases somewhat less so, typhoid fever remaining the same. In the 21 cities and towns of Massachusetts, with an estimated population of 912,900, the mortality from consumption and lung diseases was greater than for the previous week. Diphtheria continues widely prevalent; scarlet fever is especially so in Fall River and Holyoke; no deaths from small-pox.

For the week ending December 6th the death-rate in Brussels was 29.1; Antwerp 23.9; Ghent 27.6; Liege 22.5; in 21 other large towns 28.4; in 20 smaller towns 27.7. In the 45 cities and towns, with an estimated population of 1,436,959, there were 125 deaths from pneumonia and bronchitis, 74 from pulmonary consumption, 53 from diarrheal diseases, 19 from whooping-cough, 17 from small-pox (in small towns mostly), 13 from croup, 12 from fever, eight from measles, five from scarlet fever.

In 142 German cities and towns, with an estimated population of 7,390,499, the death-rate was 25.9 against 23.2 of the previous week. Three thousand six hundred and eighty-six deaths were reported; 1691 of children under five years of age; consumption 490, acute diseases of the respiratory organs 393, diphtheria and croup 183, diarrheal diseases 163, scarlet fever 74, measles 64, whooping-cough 64, typhoid fever 57, puerperal fever 21, typhus fever one, small-pox none. The death-rates ranged from 14.2 in Nuremberg to 34.6 in Erfurt; Dantzig 24.7; Breslau 24.8; Munich 33.5; Dresden 22.0; Berlin 25.1; Leipzig 23.2; Hamburg 27.7; Hanover 15.6; Bremen 15.7; Frankfurt 24.8. In the same week, Vienna 27.0; Paris 26.5; Prague 37.0.—small-pox being mildly prevalent in the three cities.

For the week ending December 13th, in the 20 English cities and towns, with an estimated population of 7,383,999, the death-rate was 30.6 against 27.4 of the previous week. Four thousand three hundred and twenty-two deaths were reported: 777 from diseases of the respiratory organs, scarlet fever 188, measles 179, whooping-cough 127, diarrheal 39, fever 34, diphtheria 18, small-pox (London) three. Scarlet fever continues very fatal in Lon-

don and Liverpool; measles in London, Leeds, Birmingham, Nottingham, and especially Liverpool. Lung diseases were more fatal than at any time since 1874. The death-rates ranged from 17.8 in Sunderland to 41.4 in Liverpool; London 30.7; Bristol 27.6; Birmingham 33.4; Leeds 31.5. In Edinburgh 25, Glasgow 31, Dublin 44 (scarlet fever being very prevalent and small-pox declining). In the 20 Swiss towns, with an estimated

population of 445,790, the mortality from lung diseases (30) and diphtheria (11) was high; diarrhoeal diseases were fast declining; fever caused three deaths, scarlet fever three, measles two, small pox (Lucerne) one.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM DECEMBER 27, 1879, TO JANUARY 2, 1880.

VOLLUM, E. P., major and surgeon. Relieved from duty in connection with inspection of veterinary supplies, and to resume his station at Jefferson Barracks, Mo. S. O. 291, A. G. O., December 29, 1879.

BARTHOLOMEW, JOHN H., captain and assistant surgeon. Granted leave of absence for six months. S. O. 290, A. G. O., December 24, 1879.

WHITE, R. H., captain and assistant surgeon. Relieved from duty in the department of Texas, to proceed to New York city and report by letter, upon arrival, to the surgeon-general. S. O. 293, A. G. O., December 29, 1879.

TAYLOR, B. D., first lieutenant and assistant surgeon. To report in person to commanding general, Department of the East, for assignment to duty. S. O. 292, A. G. O., December 27, 1879.

HALL, WILLIAM R., first lieutenant and assistant surgeon. Relieved from duty in the Department of the Columbia, and, upon expiration of his present leave of absence, to proceed to New York city, reporting his arrival, by letter, to the surgeon-general. S. O. 293, A. G. O., December 29, 1879.

APPEL, D. M., first lieutenant and assistant surgeon. Relieved from duty in Department of the Missouri, and, upon expiration of his present leave of absence, to proceed to New York city, and report by letter, upon arrival, to the surgeon-general. S. O. 293, C. S., A. G. O.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE WEEK ENDING JANUARY 3, 1880.

SURGEON W. J. SIMON detached from the Alliance and waiting orders.

Passed Assistant Surgeon H. C. ECKSTEIN ordered to the U. S. S. Alliance.

Assistant Surgeon C. J. NOUSE detached from the Tallapoosa and ordered to the Naval Hospital, Washington, D. C.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, OCTOBER 1, 1879, TO DECEMBER 31, 1879.

BAILLIACHE, P. H., surgeon. Relieved from duty, port of New York, and ordered to Philadelphia, temporarily, thence to resume his duties as member of the National Board of Health. October 25, 1879.

HUTTON, W. H. H., surgeon. Relieved from duty, port of New Orleans, and ordered to Detroit. November 1, 1879.

FESSENDEN, C. S. D., surgeon. Relieved from duty, port of Portland, Me., and ordered to New York. October 25, 1879.

DOERING, E. J., surgeon. Relieved from duty, port of Philadelphia, and ordered to Portland, Me. October 25, 1879.

ACSTIN, H. W., assistant surgeon. Relieved from duty, port of Key West, and ordered to New Orleans. November 1, 1879.

STONER, G. W., assistant surgeon. Relieved from duty, port of Buffalo, and ordered to Philadelphia. October 25, 1879.

FISHER, J. C., assistant surgeon. Detailed as chairman of board for the physical examination of candidates for promotion in the revenue marine service. November 20, 1879. Granted leave of absence for nine days from December 19, 1879. December 17, 1879.

GODFREY, JOHN, assistant surgeon. Ordered to proceed to New Orleans for temporary duty during illness of Surgeon Austin. December 29, 1879.

GOLDSBOROUGH, C. B., assistant surgeon. Detailed as recorder of board for the physical examination of candidates for promotion in the revenue marine service. November 20, 1879.

WHITE, R., JR., assistant surgeon. Ordered to Buffalo October 24, 1879. Orders to Buffalo revoked; ordered to report to Surgeon Fessenden, New York, for duty. November 12, 1879.

LEWIS, FAIRFAX, assistant surgeon. Upon expiration of leave of absence to proceed to Charleston, S. C. October 31, 1879.

GLAZIER, W. C. W., assistant surgeon. Relieved from duty, port of Charleston, S. C., and ordered to Key West, Fla. October 31, 1879.

COOKE, H. P., assistant surgeon. Relieved from duty, port of Pensacola, Fla., and ordered to Buffalo, N. Y. December 1, 1879.

O'CONNOR, F. J., assistant surgeon. Ordered to Philadelphia for temporary duty. November 10, 1879. Ordered to Buffalo, N. Y., for temporary duty. November 12, 1879. When relieved by Assistant Surgeon Cooke to rejoin his proper station. December 9, 1879.

PORTER, F. D., assistant surgeon. Assigned to temporary charge at Detroit Marine Hospital. October 25, 1879. When relieved by Surgeon Hutton to proceed to Chicago, and report for duty to Surgeon Miller. December 17, 1879.

ACSTIN, H. W., surgeon. Promoted to be surgeon from November 1, 1879. November 3, 1879.

GASSAWAY, J. M., passed assistant surgeon. Promoted to be passed assistant surgeon. December 12, 1879.

SMITH, HENRY, passed assistant surgeon. Promoted to be passed assistant surgeon. December 12, 1879.

STONER, G. W., passed assistant surgeon. Promoted to be passed assistant surgeon. December 12, 1879.

ELLISWOOD, C. N., surgeon. Resignation accepted, to take effect October 2, 1879. October 2, 1879.

BROWN, J. A., surgeon. Resignation accepted, to take effect November 1, 1879. November 7, 1879.

DANA, C. L., assistant surgeon. Resignation accepted, to take effect November 15, 1879. November 11, 1879.

Original Articles.

THE RELATION OF DRUG MANUFACTURERS
TO THE PROGRESS OF THERAPEUTICS.¹

BY ROBERT T. EDES, M. D.,

Professor of Materia Medica in Harvard University.

THE vivacious young man, with cordial grasp of the doctor's hand, his pockets laden with boxes, bottles, and books, fluent of tongue, and with no insignificant buccinator development, who represents the house of Smith, and without wishing to say anything against the houses of Brown and Jones only wants you to "just try" the beneficent Smith's gelatine-coated pills against the sugared *dragées* or gluten-covered granules of his unscrupulous rivals, and who merely calls your attention in passing to a few specifics for incurable diseases, is in some respects an instructive phenomenon.

I do not know whether he pursues his prey in Boylston Street, where game is plenty but possibly shy, or whether he pervades chiefly the rural districts, to lie in wait for the guileless practitioners of Roxbury and Dorchester. However this may be, his employers spread abroad their nets through the medical journals, near and far, and for great and small.

Our magazines, with their dense, hypertrophied, colorized capsules of advertisements, often extending like an interstitial inflammation within the somewhat scanty and anemic medical parenchyma, represent a pathological state of professional nutrition.

At first sight it might appear as if the young man were simply a nuisance, and the waste-paper basket a sufficient refuge from the circulars. This growing custom, however, it seems to me, rises almost to the dignity of a deliberate insult to the profession, and its results are a distinct hindrance to the progress of rational therapeutics, like those of homeopathy, or any other system which induces the laity and no inconsiderable part of the profession to believe that specific cures are yet to be found for all diseases, if we look long enough.

I say it is almost an insult, because even a skillful and honest chemist, if only a chemist, is not in a position to instruct us in pathology and prognosis; and the case becomes infinitely stronger when we have for our would-be teachers *unskillful* chemists and manufacturers anxious only to make money. Even this is by no means unbearable, for there is no reason why druggists should treat us with any more respect than clergymen, lawyers, authors, and old women do, whose teaching capacity seems to rise in inverse proportion to the amount of study given to the subject.

We could easily bear the annoyance of having these gentlemen hunting over our grounds so long as they carried on the amusement at their own expense and got nothing. But that is not the case. It is pretty clear that the wholesale drug dealer will not put his money where it is not likely to come back again, and the fact that the practice continues and is growing shows plainly enough that the appeal to the practitioner by garbled quotations and baseless or exaggerated statements is a good paying investment. Indeed, some manufacturers, like the large publishers, send out a regular periodical with a few pages of borrowed articles to float the advertisements, and even

provide an employee of the firm with a cheap medical education in order to have it edited by an M. D.

I have within a few months been a member of a committee to ascertain the views of the members of the Massachusetts Medical Society in regard to new preparations to be put into the pharmacopœia. Many of the replies we received said in effect, "Give us something shorter and more practical. Discard the useless and superfluous drugs, and let us have a good working pharmacopœia." And yet others contained lists of drugs to be introduced, apparently derived from the advertising sheets, some of them so recent that there has been no time for the formation of a really valuable professional opinion about them. The evidence in favor of a large number of drugs which would have to be discarded in order materially to reduce the pharmacopœia is of exactly the same kind, just as abundant and possibly more trustworthy than that adduced in favor of the new remedies. In fact, the pharmacopœia consists largely of preparations which might be considered, so far as their therapeutic action is concerned, duplicates, and many of the proposed additions, although new, botanically speaking, are not different enough in a chemical way to prevent their being placed in well-established classes. Astringents, aromatics, bitters, for instance, are natural groups containing many members already, to which there is no real utility in making additions, and from which many might be discarded without serious loss, except that of variety of name, or sometimes of taste.

The three solanaceæ — belladonna, hyoscyamus, and stramonium — might be practically represented by the alkaloid atropia, while even the new alkaloid duboisia resembles it so closely in its mode of action, though with somewhat increased intensity, that it can hardly be looked upon as an important addition to our armamentarium.

As regards the multiplication of *preparations*, it is a matter chiefly of convenience in prescribing. If one has in his pocket one vial of morphia and another of sulphate of atropia, he has all that is essential in thirty-two official preparations.

From the mercantile point of view, judicious advertising is of course perfectly legitimate. The essential of a good salesman is understood to be that he can sell people what they don't want; anybody can sell them what they do. I have less fault to find with the sellers, except those of them who are physicians, and who are supposed to be governed by a different code of morals, than with the buyers who make their advertising profitable. The mistake made by what we can hardly help considering no insignificant part of the profession is that they allow themselves to receive as scientific evidence the artfully contrived assertions of interested tradesmen. The whole system is commercial, and has but the remotest relations to scientific medicine, — relations, however, which manufacturers are obviously anxious to make appear more intimate. Does any one believe that eundrango has disappeared from the druggists' lists because *they* have become convinced that it is a worthless fraud, or because they find they can't sell it?

It might be supposed that this plan had the one advantage that under it the worthlessness as well as the value of any new remedy would be more rapidly established; but this is really of little account, for the number of possible new remedies is so immense that the busiest practitioner could not begin to keep in sight the half of them if he attempted anything like a rea-

¹ Read before the Boston Society for Medical Improvement, December 22, 1879.

sonable trial thereof. The thousands of botanical species untried, or tried and forgotten, the almost infinite combinations of organic chemistry, render any attempt at exhausting them one by one absolutely hopeless, while we are certainly not as yet in a position to study them by families and orders.

The study of drugs should begin with the medical profession, but in this study the pharmacists have a legitimate function to perform, far more important, but less profitable, than the impertinent intermeddling of which I have been speaking. The large manufacturers have a reputation to maintain. It is for their interest to furnish, and they do furnish, standard drugs of pure quality. They cannot afford, under the sharp eyes of their rivals, to adulterate quinine, morphia, or iodide of potassium. It is not necessary for them to resort to so exaggerated and fraudulent appeals, and it is agreeable to know that success may attend a business of this kind legitimately conducted.

The one manufacturer in this country whose preparations are taken as the type of purity and excellence, and whose name is a guaranty of honest manufacture, has never resorted to any of these methods.

The discovery and isolation of the active principles of drugs are of the highest importance, as permitting a certain amount of generalization of therapeutic facts, already becoming so numerous and complicated that something of the sort is absolutely necessary to an intelligent comprehension of them. How much this isolation contributes to accuracy in dosage and convenience of administration need not be said.

In connection with the use of alkaloids, we ought to recognize the real service done by one or more of the large manufacturers in the introduction of cinchona alkaloids other than quinia. It has long been known that the other cinchona alkaloids were but little inferior, and perhaps some of them not at all so, to quinia; and yet so strong is custom that every one prescribes quinia, the consequence being that nearly all the cost is borne by this alkaloid, while the others, very much cheaper and almost as efficient, accumulate on the hands of the manufacturers. More or less indirect attempts have been made to get rid of them under the name of *sweet quinine*, which was a hydrochlorate of quinia with licorice, and cincho-quinine, which contained all the other alkaloids, with just enough quinine to swear by. These preparations, like that now made in India, where all the alkaloids are separated from the other constituents of the bark, but not from each other, were all useful if sold under their proper names; but they were falsely named, and less definite preparations than they should have been. The Philadelphia firm alluded to simply stated the facts in the case, and induced physicians to try cinchonidia under its own name.

A second illustration both of legitimate and illegitimate contributions made by the pharmacist is to be found in the history of pepsin. The foreign pepsins were sure to be expensive, inelegant, and disagreeable, and sometimes, if not always, inert. Mr. Scheffer, of Louisville, has invented a very simple method of preparation which subjects the pepsin to but few disturbing operations, and brings it into a form suitable for easy and elegant dispensing. He has also gone further and illustrated by a careful series of experiments the method of its action, showing it to be a ferment rather than a solvent, and capable of converting into peptones, under appropriate conditions, a quantity of albumen many times greater than that which it is sup-

posed to dissolve in the ordinary experiments. He also showed that certain substances presented with it make it inert. In an alkaline solution decomposition and putrefaction take place, but no digestion. Alcohol diminishes, and if in sufficient quantity prevents, its activity. Bismuth has also been shown to be incompatible therewith, and yet nothing is more common than to see elixirs of pepsin and bismuth and strychnia which darken, harden, and shrink the albumen placed in them, and which seem to render visible a condition of acute dyspepsia.

Pancreatine has been shown by Mr. Scheffer to be itself digested by pepsin, so that its chance of getting through the stomach to the duodenum, where it normally exerts its function, is of the smallest, while when combined with pepsin it must be digested as soon as the mixture becomes warm enough, in or out of the stomach, to carry on the process. Yet we see many preparations of which the chief virtue is supposed to be that they contain *all* the digestive principles. These can be active, it seems to me, only so far as they contain pepsin, and have no advantage over the simple drug prepared as it now is by Mr. Scheffer's process by a large number of pharmacists all over the United States.

The most thoroughly confusing mixture of fact and fancy, for which partly manufacturers and partly physicians, though very largely the latter, are responsible, is made by the whole series of phosphorus preparations, from phosphorus itself to the glycerite of kaphaline, alkaloidal hypophosphites, vitalized phosphites, organismal phosphites, brain phosphites, etc.

We have Thompson with free phosphorus; Churchill with hypophosphites; Dusart with phosphate of lime; Polk and Percy with various salts of phosphorus. These various preparations are represented as having a peculiar influence in promoting nutrition in general, and that of the nervous system in particular.

As is well known, the hypophosphites are supposed to have special relations to phthisis or the tubercular diathesis, and apparently still retain a place of some importance in the therapeutics of that disease. The relation to the nervous system is supposed to be established, in the first place, by the fact that phosphorus does apparently act as a stimulant. Thompson says, "It is known by experiment that a short course of phosphorus renovates the failing brain power in overwork, conferring freshness, originality, and energy on the mental processes. . . . As an occasional stimulant, as a preparation for an unusual mental effort, or as a safeguard against such nervousness, for example, as that to which a first appearance before the public lays a novice open, a large stimulant dose of phosphorus may be taken an hour or two before the trial is to begin with the greatest possible advantage."

Similar things have been said of the effects of fish diet. Professor Agassiz is to have stated before a committee of the Massachusetts legislature that fish-eating communities were above the average in intelligence. I doubt this so-called fact being a fact at all, and it is certainly interesting to know that, according to some dermatologists, this very fish diet is the cause of the prevalence of leprosy in Norway and elsewhere.

Some years ago I met with a paragraph in a daily paper, of which I regret very much that I have no copy. A French or German writer, after describing the exhilarating and even too exciting effects of a fish

diet, goes on to illustrate, with that facility so often displayed by the philosophical foreigner in accounting for American peculiarities, by saying something like this: "The Americans at certain seasons of the year assemble in large numbers upon the sea-coast to feast themselves upon a species of oyster called the clam. When they have gorged themselves with this insidious comestible they listen to the most inflammatory harangue, are ready to fall a prey to the most worthless of demagogues, and exhibit in their political vagaries the disturbing action of a diet too rich in phosphorus." Have the fish been unusually abundant on the coast of Maine during the last few weeks?

Next we hear of certain conditions of disease, debility, and depression exerting an influence upon the excretion of phosphates in the urine. Among other things we often find reference to the fact, said to be well known, that clergymen excrete more phosphates on Monday than on any other day of the week. So far as I can discover this rests solely on the authority of Golding Bird. He, however, does not speak of the total excretion of phosphates, but simply of the *deposit of earthy phosphates*, which are only a fraction of all the phosphates. And we might well doubt, too, their connection with intellectual labor when we find that the clergyman most particularly described taught school through the week, and performed service three times on Sunday, always becoming much fatigued. I have been able to find in no physiology or chemistry (with the exception of a note in Flint) any analysis or statement warranting the inference that phosphates are especially connected with mental labor. With many nervous diseases, but also with many others, their increase is seen, but the increase is neither very marked nor invariable.

Dr. Chambers remarks in this connection that the dogmatic expression of Buchner, "No thinking without phosphorus," "if taken to mean that the amount of phosphorus passing through the nervous system bears a proportion to the intensity of thought, is simply a misstatement. A captive lion, tiger, leopard, or hare, who can have wonderfully little to think about, assimilates and parts with a greater quantity of phosphorus than a professor of chemistry working hard in his laboratory; while a beaver, who always seems to be contriving something, excretes so little phosphorus, at least in the urine, that chemical analysis cannot detect it."

Flint explicitly denies the relation. Of course it may be true that the nervous tissue, when active, is more or less used up, and probably a certain amount of phosphorus is set free from its higher combinations, and becomes phosphoric acid; but many other substances are set free at the same time, and the amount of mental labor or exhaustion corresponding to a given amount of phosphorus is absolutely unknown. For all we know, an attack of cystitis may rob a man of more phosphates than the composition of an epic poem.

Byasson, quoted by Flint, says that the proportion of sulphuric acid excreted is more than doubled by mental exertion, while the proportion of phosphoric acid is increased by less than one third; so that if it is proper to give free phosphorus to supply the waste, why should we not give free sulphur also? Mrs. Wackford Squeers may have been a better therapist than she knew when she supplied the waste of nervous tissue in her unfortunate pupils with the weekly dose of brimstone and treacle.

Setting aside the phosphate of lime, which has peculiar relations to the growth of bone, both on account of the phosphoric acid and the lime, I think we shall find that there are as yet no physiological facts sufficiently definite to guide us here, and that theoretical speculation forms rather a poor basis for therapeutics; so we have to decide the matter, so far as it can be decided at all, on empirical grounds.

The advocates of the hypophosphites are not likely to forget the important fact that free phosphorus is a poison, and it certainly appears that in some cases something approaching poisoning has occurred from its use as a remedy. I have myself had a case of vomiting persisting for several days, attributable to a dose of phosphorus which, even if I made the mistake in prescribing I afterward suspected, was considerably less than Mr. Thompson says should be used in neuralgia.

These cases are exceptional, to be sure, but as the phosphorus is far from being a specific, it is fair to set off the *chances of poisoning* against the *chances of cure*. Whether there is any danger of causing chronic renal disease by its long-continued use, a calamity of considerable magnitude, which Professor Percy seems to think is immediately impending or is actually upon us, I am unable to say.

The advantages of the hypophosphites, that is, of the old-fashioned hypophosphites of Churchill, may very properly be considered with those of the vitalized hypophosphites of Percy, or glycerite of kaphaline of Polk. Indeed, the evidence in favor of the latter is largely founded upon the use of the former. The managers of the present phosphite "boom" say in effect: If Churchill obtained such wonderful results with his crude and imperfect hypophosphites, how much more can we do with our organismal or vitalized preparations? But that they have done any more they have hardly attempted to show, so that I think we shall do no great injustice if we consider them together. Opinion has been greatly divided as to the value of hypophosphites in phthisis. Churchill complained, and with some apparent justice, that the early trials made with them were insufficient, but this can hardly be said now. Any remedy which offers even a reasonably small chance of success in phthisis is sure to be tested at length and on a large scale, and the mere fact that the hypophosphites have not received the high position at first claimed for them is pretty good proof that they are not entitled to it.

Most writers on phthisis assign a certain value as tonics in some cases to the hypophosphites, but not one, with the exception of Churchill, gives them a position approaching that of a specific. Yet a little circular advertising the alleged new form of hypophosphites contains such a sentence as this, extracted from one of Churchill's works: "Within the last ten years there has been an appreciable falling off in the mortality of consumption. That the use of this remedy is the real cause of this decrease is shown by Dr. Bennett's confessing that he has given the hypophosphites to a large proportion of his patients, and that nearly fifty per cent. of those so treated have got well. Dr. Williams acknowledges that with cod-liver oil alone, previous to 1862, he had not cured two per cent. of his patients; that when the oil fails he finds the hypophosphites to succeed; and that since 1862 (that is, since the introduction of the hypophosphites) he has cured seventy-five per cent."

Bennet, to be sure, does make a statement which can be, but ought not to be, construed as above. He says: "Were I only to quote the successful cases that I have had under my care, the cases in which the lung disease has been arrested and even cured, I could quote many instances of cure, myself included, which have apparently taken place under the influence of the hypophosphites, as they were long and constantly administered. But, on the other hand, I have quite as many, perhaps more, cases of death to narrate in patients whose condition admitted of recovery from the extent of the disease, and who perseveringly took the hypophosphites from the beginning to the end."

This, it will be observed, represents only the cases which were in the beginning of more favorable prognosis, and especially does not say anything about the cases which took hypophosphites, but did not persevere in their use to the end.

Later he says: "Although not admitting that phosphorus and its preparations are an antidote to pulmonary phthisis,—for I have seen too many cases of failure to be able to admit it,—I believe that they constitute a valuable medicine in asthenic disease, including pulmonary phthisis."

As to Williams, I cannot make out where anything like the statement quoted was found. Presuming the reference to mean Dr. C. J. B. Williams, of London, who published in 1871 a book on phthisis, reprinted here in 1872, we may judge by the following extracts how far he is from making any such statement as that attributed to him: "Of all means hitherto tried for the relief of the consumptive, unquestionably cod-liver oil has been found the most successful. This I stated in 1849, after three years' trial of its use; and so I repeat, after a quarter of a century's experience, that it is the only agent in any degree deserving the title of remedy in this disease."

Of the hypophosphites he says: "I have been convinced of their utility as an aid to cod-liver oil and phosphoric acid in the treatment of phthisis. I am therefore very glad to avail myself of the hypophosphites as a supplementary aid in the treatment of phthisis. I have thought it right to try them myself, both as a substitute for the oil and in addition to it. In the former way the results have not been generally satisfactory; the hypophosphite does not disagree, but there is no marked improvement as under the oil, and when they have been doing well under the oil the patients generally lose flesh and strength when the hypophosphite is substituted for it."

I have not intended, except incidentally, to state an opinion as to the value of the hypophosphites, but only to show the character of the evidence presented by the manufacturers. The authors quoted, Bennet and Williams, represent probably the most favorable class of opinions, sustained, it is fair to say, by many others.

Phosphorus, which is dangerous, and the hypophosphites, which are not, may be looked upon as stimulants, or, under some circumstances, as tonics; but that they stand in any special and peculiar relation as nutritives to the nervous system is as little proved of them as of opium, alcohol, ether, tea, coffee, cannabis indica, and perhaps many other drugs.

The clinical evidence brought forward in favor of the vitalized phosphates is hardly worth considering in the face of the garbled extracts I have read. Nor is it worth while to go into certain other details to show how Professor Percy's collaborator accepts and pub-

lishes at length the favorable judgment of Polk so long as he is willing to keep in a secondary position, and how a little later Professor Percy, apparently irritated by certain assumptions of priority on the part of Polk, takes to task the medical journals for publishing the papers of this Professor of Surgery in the Eclectic Medical College of Philadelphia, exposes his "jargon of bad chemistry," "the most laughable chemical nonsense of the day," and says it is evident that "his formulas are but the emanations of his imagination."

Of Professor Percy's own chemistry I, not being a chemist, speak with diffidence. I cannot make out what these vitalized hypophosphites are, though I suspect them to be some preparation of wheat. I have written to him twice to ask, and to my second letter, which fell into the hands of the manufacturer, I got an answer, but the chemical questions I asked, which the chemist might be supposed capable of answering, were ignored, and the letter filled with the usual stories of infants at the point of death, etc., which you all know so well.

I cannot resist one specimen of careful clinical observation from the circular above quoted: "A little child, at a large hotel, was troublesome night after night, disturbing every one within hearing. I was asked to see the child, and found it nursed by a little woman sixteen years of age, who had not yet done growing. She could give the babe no phosphates in her milk, needing all for her own development; and seeing the necessity for that I mixed the vitalized phosphites with some sugar, and tied it up in some little bags, which the child sucked. From that time it improved, and over three hundred guests in that hotel could testify that the child slept well and gave no further trouble at night." Was ever "sugar teat" so glorified?

What I have written, Mr. President, is but a small part of the subject, and intended only to illustrate how pharmacists may contribute to the advance of therapeutics, which must progress, not by the rapid discovery of many new remedies, but by a careful chemical and physiological study of a few, followed by the final test of careful and unprejudiced clinical trial. By chemical study I do not mean vague chemical speculations, which may be interesting, and may even lead to something better, but which are absolutely unreliable practical guides, nor do I mean by clinical observation the hasty inferences of the first practitioner who happens to see a patient get better after taking a supposed new remedy. The subject is difficult enough under the most favorable circumstances, and is infinitely complicated by the misstatement of supposed, inefficiently observed facts, and such misrepresentation of evidence and opinions as I have given examples of.

When the pharmacist informs us of active principles, or gives us preparations honestly representing a drug, he does good service; but when he tells us why they act or when they should be used, he is going beyond his province. Of course the pharmacist or the manufacturer may, if he please, study physiology or medicine, and his opinion is then entitled to the weight which the quality of his work warrants; but when, while remaining only a pharmacist or a manufacturer, he assumes a knowledge of sciences outside his own, and when he imports into what should be scientific regions the manners and morals of trade, he becomes a distinct hindrance to the progress of therapeutics.

ON STRANGULATED VEINS OF THE UTERUS AND THE IMPORTANCE OF RESTORING THEIR CIRCULATION AND FUNCTION OF DRAINAGE, THEREBY PREVENTING ENGORGEMENT AND MORBID NUTRITION.

BY T. H. BUCKLER, M. D., BALTIMORE, MD.

ANATOMY OF THE UTERUS.

NOT only has the anatomy of the uterus been neglected by the best observers, but the relations of its different structures each to the other have, strange as it may appear, been entirely disregarded, and hence aetiology, rational therapeutics, and surgery, which follow in the wake of anatomy and physiology, have failed to suggest the easiest and simplest methods of preventing and of treating easily its various maladies. The publication of William Hunter's plates of the gravid uterus, in 1774, was a bold step in the right direction, but since that time the pace of inquiry has been lagging, and, with the exception of the discovery of the Graafian vesicles, little of importance has been added to the knowledge on the subject which then existed.

It is well known that the greatest diversity of opinion has existed, and still exists, as to the character and composition of the uterine structures, and that this is especially the case in regard to the fibres constituting the walls of the uterus, their nature and their arrangement. J. F. Meckel gives the names of eminent observers, Walter and Blumenbach amongst others, who openly deny the existence of a fibrous structure, the contrary of which is admitted by him and many other good authorities. While most writers speak of the inner lining of the uterus as a mucous membrane, Madame Boivin has formally declared her opinion to the contrary; she has also given a most complicated account of the distribution and interlacing of the different muscular layers and fasciculi entering into the material of this organ. But as to what end and in what direction these muscular fibres exert their powers, writers generally are still more unsatisfactory, except that most of them say in general terms that these muscles contract in at least two directions, a longitudinal and a transverse. Ruysch admits only a single circular muscle situated at the base of the uterus; while Meckel, on the other hand, pronouncing this description inexact, and denying the existence of the single circular muscle of Ruysch, says that there are at the fundus of the uterus two distinct sets of muscular fibres surrounding the openings of the Fallopian tubes, but as these have to do with fecundation and the movements of the female ova-spermatozoons, they do not directly concern our present object further than the effect their morbid contraction exerts in producing congestion in the veins and erectile tissues connected with the broad ligaments, Fallopian tubes, and ovaries.

Fortunately, at this stage of doubt, confusion, and uncertain knowledge in regard, at least, to the muscular structure of the vaginal portion of the uterus, Meckel advanced partially, and Sir Astley Cooper came also to the rescue. The former says, "The oblique fibres do not exist in the neck, which, however, is composed, at least frequently, of several superimposed layers of transverse and longitudinal fibres." Now, common sense tells us that these transverse fibres, interlaced with longitudinal filaments and continued around the neck, can form nothing else than a circular muscle. A bracelet made of links and loops, or of interlaced strips

or threads, is as much a band for the arm as if it were fashioned out of one or more continuous wires, and the same is true with regard to the fibres entering into the structure of this muscle. Among Sir Astley's plates is an engraving of a uterus, which had been macerated and prepared by himself. This pyramiform figure exhibits from a little below its middle third longitudinal bands extending quite over the body to like points on its opposite side, and knit together by oblique and transverse fibres into the form of a truncated conoid. Commencing where the longitudinal fibres are lost to sight is a broad, circular muscle passing around the body and neck to within a line of the os tincæ. These fibres, superimposed on each other, and fastened together by interlacing with the longitudinal filaments, are thickest just where the neck joins the body of the uterus, but become thinner and thinner as they spread from that line upwards and downwards, till reduced above and below to a single layer of fibres.

It is perfectly evident, however, that both these eminent observers, Meckel and Sir Astley Cooper, were ignorant, as others have since been, of the vast importance and value of this anatomical arrangement in a pathological, aetiological, and surgical point of view. The outer layer of longitudinal fibres and the upper spread of circular fibres interlace, as do also the middle longitudinal with the central circular. But the innermost and thickest layer of longitudinal and oblique fibres, entering largely into the composition of the neck, is mainly connected with the middle muscular pouch or spread of fibres by oblique filaments, whereby a certain freedom of movement upwards and downwards is allowed to this internal muscular sac, fashioned somewhat like an india-rubber bottle or Florence flask. When, in a perfectly healthy uterus, the outer and middle layers of longitudinal and oblique fibres, excited through nerves from the hypogastric plexus, by prurient thought or sexual desire, contract, the thick internal layer also contracting, the cervix is driven downwards and forwards into the vagina, to the length of two, two and a half, three, and sometimes as much as four inches. But when the prurient thought ceases, or the orgasm in sexual intercourse is over, the outer and middle layer of muscular fibres relax, and the thick internal layer relaxing also the neck recedes to its accustomed position. But sometimes, while the cervix is protruded into the vagina, it is as it were lassoed or paraphymosed, and held there by tonic contraction taking place in the circular fibres surrounding the neck and lower third of the body of the uterus, and elongation of the cervix into the vagina, more or less permanent, results. In two cases of hysteria attended by metralgia, where digital examination was permitted, the neck was found protruded into the vagina about two inches in one instance, and about three in the other; these recent dislocations might have become permanent had they not been reduced by wrapping around the base of the elongated cervix a wad of cotton containing three grains of belladonna extract, which so relaxed the fibres of the constrictor cervicis that the following day the neck had receded to its place of rest. And thus the aetiology of the elongated cervix is explained without the necessity of regarding it as congenital. It was no doubt in relaxing transient contraction of the constrictor cervicis muscle that old Fraacaster, although ignorant of the mode in which his remedy acted, gave relief to hysteria by directing belladonna and lard to be applied, *cum confricatione*, to the cervix.

The word "telescoped," used to signify the extension of the cervix into the vagina, expresses the fact, but is misleading as to the mode of its occurrence. The sections of a telescope are pulled out or pushed back, whereas the neck of the uterus is thrust out by a muscular *vis a tergo*, and recedes when the fibrous contraction relaxes. Railway cars telescope because the acquired velocity of the rear carriages drives them into or through the front coaches, which, like the engine, have come to a stand-still; but we would not say that the snail telescopes from its spiral abode, or that the tortoise telescopes its head and neck out from or into its shell.

Circling through the walls and around the body of the uterus at its centre is a powerful muscular band, which on account of its importance should not remain anonymous, and may for want of a better name be called *cestus circularis* or *eucloteres* muscle. This powerful muscle, interlacing with the longitudinal and oblique fibres, acts as a point of support; thereby the latter, extending to it from the neck of the uterus in one direction, and from its fundus in the other, are enabled to act with an advantage and force in parturition which they could not otherwise have. The greatest protrusion and elongation of the neck into the vagina in a perfectly healthy unimpregnated uterus, occur from prurient excitation, causing contraction of the longitudinal and oblique fibres and consequent drawing together of the transverse, or those surrounding the cervix. The comparatively feeble and immature muscular movements of the unimpregnated uterus are contractile, protrusive, retractive, and to a limited extent vermicular. During the orgasm the uterus and appendages are in a state of organic exuberance, the muscular fibres tense, the nerves excited, the capillary circulation is active, the erectile tissues everywhere rampant; the striated lobes of the cerebellum are in a state of healthy erethism, their vessels physiologically congested, and the whole sympathetic nervous system responds. The contraction of the longitudinal and oblique fibres not only forces the neck of the uterus downwards and forwards, but by compression reduces the capacity of the uterine cavity, which, resuming its size when the orgasm is over, pumps up, as into an exhausted receiver, prostatic, seminal, or other fluids contained in the vagina. The uterus, on expanding and resuming its position, having through connection of its anterior fibres with the upper wall of the vagina this *point d'appui* only, is drawn forward on its axis, thus throwing its mouth into the posterior cul-de-sac of the vagina, and thereby aiding the suction which the cavity of the uterus, while expanding, is in the act of accomplishing, in the way that a compressed india-rubber bottle, allowed to resume its shape, pumps up any fluid at its mouth.

THE CONSTRICTOR ORIS ET CERVICIS UTERI MUSCLE.

If the circular muscle at the entrance of the gravid uterus had no other office than that of closing the mouth of the womb during gestation, the name sphincter, applied to it by recent writers, would not be inappropriate; but in emotional life proportionate to the degree of civilization, it acts by constricting the veins of the cervix, and becomes the origin and source of various uterine diseases, and therefore, so far as the cervix alone is concerned, it might be styled the *fons et origo morborum*. But as this muscle is subject to anatomical transposition, to translation of its physiological func-

tions, and has a double office to perform, one belonging to the active state of gestation, and the other to the more dormant condition of the unimpregnated uterus, a more comprehensive and discriminative name, such as *constrictor oris et cervicis uteri*, would seem to be required. This name embraces all that sphincter could signify, and at the same time expresses how its concentric action may become a factor of atresia or stenosis, with their trains of multiform and most serious maladies. All other muscles of the body having received appropriate names, it seems superlatively strange that this constrictor, or sphincter muscle, having clearly defined fibres and endowed with definite and most important functions, should have remained until now almost anonymous, and certainly without a distinctive or discriminative title.

The constrictor cervicis muscle, surrounding the neck and lower third of the body of the uterus, is proportionately never more broad than in the unimpregnated uterus, and never more narrow than at the full period of gestation, when its fibres are rolled together in the form of a ring, which, like a cord compressing the mouth of a bag, draws together the ends and loops of the longitudinal fibres and closes the mouth of the womb. As pregnancy advances, the uterine canal becomes little by little shorter and shorter, its upper portion widening more and more to the capacity of the lower half of the uterine cavity, of which it becomes a part, and, *pari passu*, with this process of transformation the fibrous walls of said canal enter into the composition of the uterus, whereby the transverse fibres connected with its two outer layers and constituting the constrictor cervicis muscle are, if it may be so expressed, shifted, slid off, or left in their relatively new situation to become during gestation the sphincter, or more discriminatively, the constrictor oris uteri. When parturition occurs the longitudinal and oblique fibres, excited to powerful contraction, draw on this ring or circular muscle, and pull it open.

In sexual intercourse the uterus protrudes its neck, and seems as though it would jump through this lasso or constrictor cervicis muscle into the vagina; whereas in the evolution taking place during gestation the reverse occurs, and the neck is drawn out, even to its very mouth, from the muscular lasso.

The constrictor cervicis muscle in the comparatively dormant state of the unimpregnated uterus bears the same relation to the constrictor vaginæ that the upper or internal sphincter has to the sphincter ani. There is another point of resemblance; each external sphincter is under control of the will, while the internal constrictors or sphincters are beyond its reach, except so far as volition is, by reflex excitomotory acts, communicated from the voluntary to the involuntary muscles.

In the formative state the Fallopian tubes, uterus, and vagina constitute one continuous cylinder or elongated pouch, afterwards divided just where the circular fibres are found into three separate compartments. In the fundus of the uterus are the circular fibres of Meckel, at its mouth the constrictor oris et cervicis uteri, and lastly the constrictor vaginæ muscles. As there is accord between the external and internal sphincters of the rectum, so there is reflex sympathetic action between the three circular muscles dominating the prime reproductive cavities; that is to say, if there is transient or tonic contraction of the constrictor oris et cervicis uteri muscle, there is also con-

responding tension in the fibres surrounding the openings of the Fallopian tubes, producing congestion in the vascular and erectile tissues existing to a greater or less extent in these latter. And where contraction of the constrictor cervicis muscle is overcome by protracted dilatation, corresponding relief is given to the contraction of the circular fibres at the fundus of the uterus surrounding the mouths of the Fallopian tubes. The constrictor vaginæ and the sphincter ani are voluntary muscles, but the interior circular fibres of Meckel are, like the constrictor cervicis and internal sphincter bands between the rectum and colon, beyond the reach of volition and subject to organic instincts alone, except when these are modified by reflexes from the voluntary muscles.

Cloacic or tonic contraction of the constrictor cervicis uteri fibres becomes, as we shall presently see, in the unimpregnated uterus, the active cause of various uterine affections. So much for the muscular arrangements and their capabilities; but it is essential to a proper understanding of the subject that we also call attention, briefly, to the vascular apparatus of the uterus and its appendages.

THE UTERINE CIRCULATION.

The reader will recollect that there is no part of the human body where the origin, course, anastomosis, and innosculation of arteries are more irregular than in the vessels occupying the cavity of the small pelvis, and, notwithstanding these variations, the compensating powers of nature are such that their ultimate distribution is as a rule accomplished with exactitude. He will also remember that the uterine artery, having its origin usually from the ischiatic, but sometimes from the pudic, takes its course with its accompanying vein between the folds of the broad ligament to the uterus, into the lateral walls of which its branches are distributed. *Now the point I wish to make, and desire the reader to note is, that some of these branches with accompanying veins for the return blood pass through and underneath the bands of the constrictor cervicis uteri muscle, which, operated on by various influences, contracts transiently, rigidly, and often permanently, so as to impede to a greater or less extent, and sometimes obstruct entirely, the return blood by the veins.* And not only are the veins compressed, but also lymphatics and branches of the sympathetic from the hypogastric plexus, and we all know how paresis of the vaso-motor nerves robs the capillary vessels of their vital powers of contraction, thereby rendering them prone to dilatation and congestion. In this way most of the ills that uterine flesh is heir to have their origin. Any other organ of the body having the venous flow of blood from it arrested, while the arterial afflux still goes on, must and does always suffer deplorable consequences, modified by the nature of the structures deluged by obstruction to the return circulation. The relations of the constrictor cervicis uteri muscle and of the primary branches of the uterine arteries and their return veins, by which latter the drainage is effected, are altogether unique.

THE CAUSE OF UTERINE ENGORGEMENT AND DISPLACEMENT.

A circular muscle arranged around the lower third and the neck of the uterus like an elastic garter, particularly liable to irritation and subsequent contraction, having direct power to impede the venous flow, and yet too weak to control the arterial circulation,

becomes, by arresting the return blood and backing it on the womb, the factor of engorgements in the neck and body of the uterus, and as a consequence is the cause of procidentia, retroversion, retroflexion, and anteversion, according to the part of the womb which is weighted by the hæmostatic engorgement. If increased bulk and consequently weight is brought about in the neck, the uterus is liable to be dragged down, like a fisher's cork with lead attached, into the cavity of the pelvis; but if the summit of the posterior, anterior, or lateral walls be the seat of the congestion or infarction and increased bulk, then the tendency, hurried by exciting causes, is to topple backwards, forwards, or to either side, according as the back, anterior, or lateral walls contain the greater weight of engorged matter. In this way, just as the fisher's cork falls in one direction or the other, as weight is added to a particular side, retroversion, anteversion, or lateral declension is brought about. The normal position of the womb in health is that of anteversion.

There is a form of lateral displacement not of necessity connected with the causes of dislocation already assigned, which Meckel describes in the following words: "When the fibres of the broad and round ligaments of one side act more forcibly than those of the opposite side, the uterus is carried transiently or permanently into one half of the pelvis, an arrangement which we have often observed, although it depends on no mechanical cause, and although the parts which serve to retain the uterus were unaltered in their texture." Again, on page 555, he mentions "the situation of the uterus out of the median line, in which case it generally rests against one of the sides of the pelvis." There is a form of strumous engorgement or infarction of the walls of the uterus rendering them and the neck extremely thick, which does not depend on the anatomical arrangement, or rather derangement, of the muscular fibres and veins about the neck of the uterus. These exceptions are here referred to for the purpose of clearing away the ground, isolating and bringing into more distinct view the subject under consideration.

FIBROID AND OVARIAN TUMORS; CARCINOMA.

Arrest of the return blood long continued causes also fibro-plastic thickening, and often permanent augmentation of bulk. And when the ætiology of fibroid tumors comes to be more carefully examined and better understood it will probably be found that their mode of production is largely due to an arrest of healthy nutrition caused by obstruction from muscular or other compression, preventing the free return of blood through the veins. Fibrine and blood globules blocked up in the capillary vessels sometimes assume a parasitical growth, and become the germs of subsequent fibroid development. The coagulable fluids found in fibroid cysts would appear to be nothing more nor less than the albuminoid reserve of blood forced into them by arterial afflux on the one hand, and obstruction to the reflow of blood through the veins on the other. In ovarian disease, on the contrary, the vessels growing with the development of the tumor are unobstructed, and accordingly the cysts are filled with non-coagulable fluids of various degrees of consistency. This muscular compression, and consequent arrest of nutrition, explains more satisfactorily than any other theory the primary origin of carcinoma. The uterus

and mammae are peculiarly the tropics of cancer, produced in the former by the obstruction of veins underneath the constrictor cervicis uteri muscle, and in the latter by compression of the corsets, after the mode in which pressure of the pipe-stem, by arresting circulation and nutrition, gives rise to cancer of the lip.

HEMORRHAGES.

Obstruction to the return blood also produces not only congestion of the inner lining membrane of the womb, but often a varicose condition of its veins, and not unfrequently this congestion and morbid repletion is relieved by profuse diapedesis, hæmorrhage from the vessels of the endometrium, often showing itself in the form of profuse menorrhagia. There is also a spongy thickening of the walls of the uterus, with more or less congestion of its inner lining membrane, from and through which is secreted and exuded a profuse mucous or sero-purulent discharge. This condition, generally called uterine catarrh, is also largely due to retardation of or obstruction to the return blood, caused by strangulation of the uterine veins by contraction, more or less transient or permanent, of the upper, middle, or lower fibres of the constrictor oris et cervicis uteri muscle. Here again relief has been unknowingly derived from the preparative operation of dilating the cervical canal, thereby releasing the compressed veins and setting free the return circulation, and not, as is generally supposed, from the topical treatment afterwards applied. Sometimes the arrest of blood only gives rise to vascular turgescence of the endometrium and the vessels of the longitudinal fibrous layers with more or less œdema of the cellular tissue in and between said layers. This morbid condition is one of the causes of sterility, and if found in the dead body is better than any other for purposes of dissection. A weight of eight or twelve drachms suspended on an india-rubber cord just capable of sustaining it will remain in a uniform position, but if an increased load be added, the cord yields and the body is let down; in like manner, the healthy uterus, sustained by the vaginal column, round ligaments, and other yielding supports, holds its place until congestion, engorgement, or infarction, adding to its weight, causes it to decline.

In so-called internal uterine hæmorrhage after parturition, what happens to produce it? While the longitudinal fibres are utterly relaxed, the constrictor oris uteri muscle has contracted, thereby not only closing the mouth of the womb, but obstructing the return blood to the general circulation by the veins. In two cases of post parturient hæmorrhage, while my hand was introduced above the line of the umbilicus, for the purpose of pulling out blood-clots, the contractile pressure of the constrictor oris could be distinctly felt grasping my fore-arm; and it was manifest that, while this muscle was sufficiently rigid to form a *point d'appui* for the longitudinal fibres to act on, the latter were too weak and relaxed to avail of the advantage. After removal of blood-clots, titillation of the inner walls with the fingers of the right hand, grasping the uterus through the walls of the abdomen with the left, and the use of ergot, both of these cases progressed favorably.

The wife of a friend of mine, living in New York, died from internal hæmorrhage, there being no outward flow of blood whatever. How could this have happened unless the longitudinal fibres were powerless

to pull open the mouth of the womb, already closed by contraction of the constrictor oris muscle? After death the uterus was found filled with coagulated blood and serum. In rare instances the contraction of the constrictor cervicis is so great as not only to obstruct the venous, but materially to arrest the arterial circulation also. Where this occurs the uterus is in the beginning voluminous; but when the arterial supply has been long cut off, it is atrophied, its tissues are wilted, and the inner lining membrane is dry, and as rough as pumice-stone; and in rasping out, as is sometimes done, this indurated surface, as well as in other intra-uterine operations, the relief comes not so much, as is generally supposed, from what is done within the cavity of the womb, but rather from the preliminary operation of dilating its cervix, and thereby unconsciously releasing the veins and arteries, arrest in the circulation of which had given origin to the trouble.

A lady had been to most of the capitals in Europe to consult, without success, gynecologists for the relief of profuse menorrhagia; finally, she went to another specialist, who, to arrest the bleeding, introduced for the first time a sponge tent into the cervical canal. Several months having elapsed, this gynecologist inquiringly wrote to a friend of his in Paris, who came to me to ask if I could explain why it was that the introduction of a sponge tent had not only arrested the hæmorrhage at the time, but had also effected a permanent cure, as shown by the fact that the catamenia had been perfectly regular for four consecutive months, of customary quantity, and unattended by the least loss of hæmorrhagic blood. In reply to the question, I said, "Obviously because the sponge tent had broken up an old stricture of the uterine canal, caused by tonic contraction of the constrictor cervicis uteri muscle, and, as a consequence, the veins returning blood from the uterus, being released from a ligature, were now performing freely their proper office of drainage." But whether the explanation was accepted, or even understood, I never learned.

TREATMENT.

Do not suppose, however, from the relief and final recovery thus obtained, that I approve of the general and indiscriminate use of the sponge and sea-tangle tents, having witnessed in several instances, both abroad and at home, deplorable consequences resulting from their employment by eminent practitioners; the expansion of either is so free, resistless, and difficult to limit that the transverse or circular fibres, instead of being gently stretched, are sometimes torn, the rude treatment often giving rise to phlebitis, followed by metritis, metro-peritonitis, pyæmia, or parametric cellulitis. Moreover, the expansion of these tents, operated by a perfectly irresistible hydraulic power, is so rapid and great that, instead of having, as before the tent was introduced, pressure of the muscle from without on the return veins, the powerful expansion of these tents causes compression and consequent interruption to their circulation and office of drainage from within. The movement of blood in these veins can go on properly only when they are nicely poised within the circular and longitudinal meshes of the constrictor cervicis fibres, and while these latter are in a state of healthy tension, or, it might rather be said, repose.

Your patient indulgence is asked in order that the easy mode of meeting all the difficulties and morbid conditions directly dependent on and growing out of

contraction of the constrictor cervicis muscle, and consequent hæmorrhage resulting therefrom, may be recounted. After carefully examining, more than forty years ago, the uterus and its appendages, and especially the topography and anatomical relations of their different structures, the practice now to be illustrated by cases briefly drawn was adopted and continuously carried out, whenever opportunities offered, with good success, and without, so far as is known, injury to a single female. It was begun on the theory that arrest of the venous circulation was the direct primary and often the continued cause of numerous morbid conditions to which the uterus and its appendages are subject. The treatment consists in the simple expedient of dilating the cervical canal, so as to overcome contraction of the constrictor cervicis uteri muscle which had narrowed or closed it, and to keep the dilator applied sufficiently long to fatigue the muscular fibres, thereby removing pressure from the veins of the neck and lower third of the body, setting free the circulation and renewing, or rather restoring, their office of drainage.

I would not for an instant have it supposed that I regard the introduction of male urethral bougies into the uterine cavity as a novelty; on the contrary, it has, no doubt, been done thousands of times, the use of these instruments always at hand as dilators being very naturally suggested. But the bougie, when used, has as a rule been introduced and withdrawn just as in the treatment of strictures of the urethra, and without regard to the anatomical relations of the uterine veins and constrictor uteri fibres, each to the other, and consequently only in a few instances, or by accident, has the bougie been permitted to remain in the uterine canal for any length of time, so as to fatigue the muscle, and thereby give lasting effect to the dilatation. And when bougies have been tried no intimation was ever thrown out that they were introduced for the purpose of releasing the cervical veins and restoring to them their proper offices. I at first used as dilators sounds made of a pliant metallic compound, and easily bent in any direction; but some time afterwards I was fortunate in procuring from the late Mr. Andrews, chemist, three sets of male urethral bougies he had brought with him from England. It was at once apparent that they were the very sort of bougies required; for, while readily bent to any curve, they were at the same time sufficiently resistant to retain their position. The largest of these — from No. 5 to No. 12, two of them being of unusual size — were used in all cases. I am referring now to a period when the treatment of uterine affections was largely in the hands of empirics, and when the women of the country were going in shoals to consult at Flatbush, near Brooklyn, New York, a medicine-man who at that time held over the hysterical provinces of this country an autocratic sway not less absolute than was the rule of Dr. Francia in Paraguay. It was to rescue this department from the hands of quacks that the late Dr. Francis and others in New York procured from the legislature of that State a bill to establish a hospital in the city of New York for the treatment of the diseases of women, placing Dr. J. Marion Sims at its head.

(To be concluded.)

—Thus far there have been nine fatal cases of diphtheria in the town of Franconia, N. H., since December 4, 1879. Population, 549.

RECENT PROGRESS IN THE TREATMENT OF CHILDREN'S DISEASES.

BY D. H. HAYDEN, M. D.

*Athrepsia*¹ (a primitive, *θρεψις*, nutrition) is the name applied by Professor Parrot, in a series of clinical lectures delivered at the Hôpital des Enfants assistés, and since then embodied in the above book, to a series of morbid processes, beginning always with diarrhoea, the essential fact of which disease is a denutrition of the infant, bringing in its train a succession of accidents which have hitherto been regarded too much in the light of separate diseases, but which it is the object of these lectures to show consist in a chain of clinical facts linked together by incontestable evidences of relationship, with a typical order of succession, and having a common origin in the disturbances of nutrition.

The definition of "new-born" is given in precise terms as including infants under two months of age, and it is with the disease as pertaining to this brief period of existence that the author's teachings have to do. The first and constant symptom of *athrepsia* is a gastro-intestinal disturbance, namely, a diarrhoea, without which, according to Parrot, there can be no *athrepsia*.

As a necessary preliminary to the intelligent study of this disease, two lectures are devoted respectively to the anatomy and physiology of new-borns. The important change from fetal life relates to the altered mode of nutrition, involving a new act, namely, digestion; and in the infraction of the natural laws of hygiene is to be found the habitual source of the digestive troubles which mark the first step towards the production of *athrepsia*.

Athrepsia is divided into three periods, and the symptoms marking these different stages are graphically described in the succeeding lectures. The initial symptom is a modification of the stools; and if the disease stops here the health is but slightly affected, and is rapidly reestablished. If the disease continues its march, the diarrhoea becomes aggravated with the addition of vomiting; and thrush, erythema, and not seldom ulcerations of the mouth make their appearance. The temperature is peculiarly variable, in a majority of cases being elevated two degrees or more, though in others it quickly falls below the normal. The pulse follows quite regularly a modification in the same direction as the temperature. Emaciation sets in rapidly, and the infant is perceptibly losing its strength. There is still hope; but one step more and confirmed *athrepsia* has entered upon its last stage. The incidents peculiar to this period, in addition to an aggravation of preceding symptoms, are described in order, and consist of diminished temperature of the breath and body, marked slowness of heart-beats, cyanosis, sclerema, modification in cranial bones, various functional disturbances of the nervous centres (atresia of pupils, coma, convulsions, generally tonic and partial, strabismus, trismus). Complications are particularly liable to supervene and carry off the patient, as pneumonia, peritonitis, erysipelas, mammary abscesses.

The study of these different symptoms is taken up in detail; and the lectures that follow on the pathological anatomy of the various lesions of the skin, mucous

¹ Clinique des Nouveaux-nés, L'Athrepsie, par J. Parrot, Professeur à la Faculté de Paris, Médecin de l'Hôpital des Enfants Assistés. Paris. G. Masson, Éditeur, Libraire de l'Académie de Médecine. 1877. One volume. 8vo.

membranes, and internal viscera seem calculated to sustain the author's views derived from the clinic.

The important conclusions therein contained may be summed up briefly, as follows:—

Thrush never exists as an independent disease, but is to be regarded as one of the earliest manifestations of atrespia. It is necessary to be on one's guard not to attribute to it the troubles which accompany it. It is found abundantly in lying-in hospitals and *crèches*, where atrespia reigns endemically.

Erythema (of the buttocks, thighs, scrotum, labia majora) assumes a grave character only when nutrition is profoundly affected, and the diarrhoea persists.

Plaques *pterygoidiennes* is the name applied to two ulcerations situated symmetrically on each side of the palate, posterior and interior to the alveolar arch. These as well as the described ulcerations of the buccal mucous membrane and of the inner mallooli are all different manifestations of atrespia.

The sclerema of new-borns is without exception a result of atrespia, and one of the terminal symptoms of the disease. It has been quite generally confounded with oedema of new-borns, which is not only an entirely different complaint, but is shown by the author to be incompatible with sclerema, the two conditions never coexisting at the same point. Microscopical examination of skin affected with sclerema (*endurcissement atreptique*) shows a desiccation with wrinkling of the layers, and a certain degree of atrophy of the fat which lincs it. There is no new formation of tissue as in scleroderma properly so called, and no serous exudation as in oedema.

The various nervous symptoms (coma, convulsions, trismus) which close the scene are all of uræmic origin, due to the suppression of the renal functions (*encephalopathie urémique*). Tetanus neonatorum is only one variety of the convulsive or eclamptic form of uræmia, and has nothing in common with tetanus proper, save the name, although the possibility of this latter disease affecting new-borns, in extremely rare cases, is not denied. The resemblance of the two is quite marked, owing to the coexistence, in the atreptic form, of induration of the skin with tonic convulsions. The natural resistance offered by infants to any attempts to open the mouth makes the likeness still stronger.

The pathologico-anatomical changes in the brain in the later stages of atrespia are various (steatosis, softening, hemorrhage); the nervous symptoms alluded to above, however, cannot be referred to these lesions, inasmuch as the latter are often well marked in patients exempt from all cerebral manifestations; and, on the other hand, it is not rare to find these symptoms where the autopsy fails to reveal any of these alterations. In the brains of atreptic infants two pathological conditions are constant,—diffuse steatosis and congestion. The above-mentioned nervous symptoms are referred by Parrot for their explanation to the changes in the blood (anæmia, uræmia, and loss of watery constituents), as being more important factors in their production than the cerebral lesions.

The uric acid infarctions found in the kidneys of new-borns are, according to Parrot, and in opposition to Virchow and others, essentially pathological, and an habitual consequence of atrespia. In corroboration of these views are cited: (1.) The absence of conclusive proof to the contrary by means of autopsies upon

infants who have died in perfect health. (2.) A series of examinations by himself of new-born birds, when these necessary conditions could be fulfilled, showing invariably an absence of any infarctions of the tubules of Bellini.

The first step, therefore, in atrespia is a vicious digestion, followed by insufficient alimentation, which extends gradually to the whole organism. The ingesta first diminish, then stop. The protein tissues and fat are burned. The individual consumes itself, and the limit to which autophagy can be carried decides the term of existence; and there is no clinical fact that is not determined by this subversion of nutrition. This is the essence of the disease and the diarrhoea applies the torch.

The name atrespia, it is thus seen, is not given by Parrot to a pathological unity, but to a succession—to a progression of morbid acts, which, while they have a common seal, are evolved in an independent manner, since the first can have disappeared (the diarrhoea, for instance), when the fatal termination is imminent.

These various "morbid acts" (diarrhoea, thrush, erythema, ulcerations of the skin and mucous membranes, sclerema, coma, convulsions, tetanus, uric acid infarctions), the author complains, have been distributed by writers on diseases of infants too much at haphazard, through their books, as isolated facts, creating as a result much nosological disorder, the source of grave and numerous errors.

In the chapter devoted to treatment Professor Parrot has shown himself alive to the all-importance of hygiene; and in addition to the treatment of atrespia proper we have an enlightened treatise on matters pertaining to the management and feeding of infants in health.

Cyanosis Afebrilis Icterica Perniciosa cum Hæmoglobûria.—Under the head of "A Hitherto Undescribed Endemical Disease of New-Borns," Professor Winckel¹ describes an epidemic, very fatal in its character, which broke out in the Lying-In Hospital of Dresden, affecting in rapid succession twenty-three infants. The disease made its appearance most frequently on the fourth day, in one case as early as the first day, and its average duration was thirty-two hours. With the exception of five who were being artificially fed, they were all being nursed by their mothers, who were healthy and free from any suspicion of disease. Nineteen of the infants thus affected died. Only one was discharged well; two were still sick when discharged; and one was materially improved. There was nothing in the nature of the confinement or in the previous condition of the infant to give any clue to the nature of the disease.

The peculiar symptoms characterizing the disease were: cyanosis, icterus, sighing respiration, hæmaturia, rapid lowering of the temperature (except in one case, which gave 100.5° F. by thermometer in the rectum). The blood presented important changes, being of a blackish-brown color and of syrupy consistence, and showed, in addition to a marked increase of the white corpuscles, a mass of fine granules, composed in part of the detritus of the red corpuscles, in part showing a molecular movement. Towards the end, clonic convulsions of the upper and lower extremities and marked twitchings of the muscles of the eye, with convergent strabismus, made their appearance.

¹ Deutsche med. Wochenschrift, Nos. 24, 25, 1879.

In only one autopsy was there found an arteritis, having its point of departure from the umbilicus. The liver was much swollen, of a dark brown color, showing on sections here and there yellow streaks, and often granular detritus, but not always. There was no fatty degeneration of the heart. The spleen, without exception, was enlarged and thickened, and of very firm consistence. The cortical substance of the kidney was brown in color, and infarctions of hæmoglobin were found filling the papillæ. There were ecchymoses throughout the whole length of the intestinal canal below the duodenum; also in the lungs, heart, diaphragm, and pleura. There was enormous swelling of the mesenteric glands, as well as of Peyer's patches; also a moderate hyperæmia of the mucous membrane of the bronchi and larynx, and numerous hæmorrhages in the œsophagus and in the posterior wall of the pharynx. The brain was often considerably œdematous, with dilatation of all the ventricles.

The question therefore, according to Winckel, concerns a disease, in all the cases, which cannot have been caused by puerperal infection, nor by medicaments, nor by the food. In the absence of any ætiology, he proposes the name "cyanosis afebrilis icterica perniciosa cum hæmoglobiuria."

[These cases of Winckel resemble in many of the symptoms and post-mortem appearances an epidemic which occurred at the Boston Lying-In Hospital in 1873, and which was reported by Dr. W. S. Bigelow in the JOURNAL, March 11, 1875, page 277. In Winckel's cases, however, there was no diphtheritic inflammation of any mucous membrane, which was a prominent symptom in those described by Dr. Bigelow. There is also no mention by Winckel of the presence of micrococci, which were found in large numbers in the other cases. — REP.]

*Icterus Malignus Neonatorum.*¹ — Dr. Birch-Hirschfeld, at a meeting of the Gynecological Society, held March 6, 1879, at Dresden, read a paper upon the different forms of icterus of new-borns. Under the head of icterus perniciosis he classed those forms of syphilitic origin which arise from a pylophlebitis. To the icterus of new-borns, with acute fatty degeneration, which had particularly occupied his attention, he would give the name icterus septicus. In the autopsies made by him at the Lying-In Hospital at Dresden, sixteen per cent. of all the infants had icterus; and in many of the cases there was found a suppurative of the navel, in by far the greater number of cases there being an arteritis, much seldom a phlebitis umbilicalis. Notwithstanding the rarer occurrence of the latter, the reader believed the umbilical vein to be the canal for the entrance of infection; and called attention to the fact that communication of this vessel with the circulation does not cease immediately after birth, but that an alternating emptying and filling takes place, corresponding to the different phases of respiration and of the heart's action. The non-entrance, as a rule, of a thrombus into the vein explains why the infectious matter entering it does not excite a phlebitis, but is carried into the liver; whereas, on the contrary, the same matter, entering the umbilical arteries, which contract firmly, and in which thrombi are formed, excites a local arteritis. In the liver the septic poison causes an interstitial and parenchymatous inflammation, which finally leads to a breaking down of tissue. From here as a starting-point the icterus is to be explained; but it is

not to be regarded as a hæmatogenous icterus. In infants the parenchyma of the brain is found icteric, which is not the case in adults. At the same time, in many of these cases (thirty-three per cent.) there are developed perivascular herds, consisting of thickly congregated granular cells, which have never been observed by him in infants not icteric. Whether this encephalitis in form of herds is due to absorbed gallic acid, or is to be attributed to some other matter resulting from the broken-down parenchyma of the liver, remains undecided. In a few cases the development of large quantities of micrococci could be demonstrated four hours after death in the umbilical vessels, liver, brain, and blood.

In the debate that followed, Dr. Münnel expressed the belief that trismus neonatorum had a causal connection with this septic encephalitis. Dr. Winckel shared in this opinion, and was inclined to associate the erysipelas neonatorum with the icterus arising from the absorption of septic matter.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. G. CUTLER, M. D., SECRETARY.

PHLEBITIS OF THE RIGHT LATERAL SINUS AND EMISSARY MASTOID VEIN.

DECEMBER 22, 1879. DR. J. O. GREEN reported the case. There had been otorrhea for many years, and within a short time pain in the ear, vertigo, and vomiting. After the patient entered the hospital, the subjective symptoms were pain at the top of the head and in the mastoid region, chills and high temperature; while the objective symptoms were great tenderness of the mastoid, with tenderness and œdematous swelling along the base of the skull, without fluctuation, the most sensitive spot being just over the point of exit of the emissary veins. Later the mastoid cells were opened by boring, with relief to the pain in the head, and to the mastoid tenderness; there was swelling and induration down the neck along the sterno-mastoid muscle. The symptoms and temperature allowed a diagnosis of pyæmia, which was confirmed by autopsy. Beneath the periosteum, at the point of exit of the emissary vein through the skull, pus exuded freely, and the tissues at the base of the skull were infiltrated with pus. The bone in the sulcus of the right transverse sinus was slightly eroded as far forward as the junction with the cavernous sinus. The sinus had thickened walls, and was lined by a softened adherent thrombus. There was a small carious spot in the petrous portion of the temporal bone, over which the dura mater was discolored. Metastatic abscesses were found in the lungs, and in addition cloudy swelling of the liver and kidneys and splenic tumor.

OVARIAN CYSTS.

DR. JOHN HOMANS showed ovarian cysts removed from three patients by ovariectomy. The first was a multilocular cyst of the right ovary, taken from a married woman, forty-one years old. The second was a dermoid multilocular cyst, likewise of the right ovary, removed from a single woman, twenty-four years old, and practically a solid tumor. The third was a multilocular cyst of the left ovary from a single woman, thirty-three years old, removed the day before. In the

¹ Berliner klinische Wochenschrift, August 4, 1879.

first case there were no adhesions; the operation was quickly and successfully finished without the loss of half an ounce of blood, and the pedicle, which was broad, was secured by being perforated twice with double catgut ligatures, and doubly encircled by two others. There was no bleeding from the stump when it was examined, just before sewing up the wound; but the patient died of hemorrhage during the night following the operation, the Fallopian tube and a vessel having in some way got out of the loops of the knots. When Dr. Homans left the patient he feared he had tied the pedicle too tight, and that there might be sloughing. Possibly an attack of vomiting loosened the ligatures and slipped them off; or perhaps the pedicle was oedematous and shrunk after the removal of the tumor, and so allowed a portion of the constricted part to slip out. The second case was eminently successful, the temperature becoming normal on the fourth day, and the patient leaving the hospital in less than three weeks. In this case there was no hemorrhage, as the pedicle was constricted very tightly with Dawson's clamp before tying. Dr. Homans had always done this in his earlier cases, but having tied the pedicle in halves without constricting by a clamp in four successful cases, he had begun to think that instrumental compression was unnecessary. He said that he should not omit it in future. In addition to ligaturing the pedicle in this manner, five vessels in the end of the stump were tied separately with silk. Several temperature charts of this case and of others were shown.

The third case, operated on the day before, was so far doing remarkably well; the cyst, which was shown, was a multilocular one of the left ovary, and in one place had begun to suppurate. The adhesions to the mesentery and the small intestine were very broad and vascular, and were separated by ligatures of silk or catgut and Paquelin's thermo-cautery. The pedicle was tied in a "clove-kitch," as Lawson Tait has recently suggested and practiced, and the vessels mentioned in the last case, which always seem to be pre-sent in about the same number, were separately tied with silk, although this was probably unnecessary. The operation lasted an hour.

THE RELATION OF DRUG MANUFACTURERS TO THE PROGRESS OF THERAPEUTICS.

DR. R. T. EDES read a paper on the Relation of Drug Manufacturers to the Progress of Therapeutics, which is printed on page 49.

In commenting, Dr. MINOT thought that so admirable a paper left but little to be said on the subject. There was a distinction to be made between pharmaceutical chemists and manufacturers, though they were often, perhaps generally, united. Without the former we should never have had morphia, quinia, ether, salicylic acid, and a thousand other chemical products, which were almost indispensable in the practice of medicine. But the pharmacopoeia was always overburdened with articles, many of which were useless; there were upwards of forty official preparations of iron alone, of which two thirds, at least, were superfluous. It was important to the manufacturer that his goods should be appreciated and employed, and he naturally availed himself of the well-known tendency of the human mind to attribute recovery to treatment, and urged the employment of his preparations upon the profession, often with the addition of an imperi-

nent lecture on pathology and therapeutics. This could not fail to retard the progress of the healing art, which could be advanced only by careful observation and experiment, coupled with a thorough knowledge of the natural history of disease, and was hindered by a desire to try new remedies without carefully testing the result, as well as by the too common habit of publicly recommending medicines after a very brief acquaintance with them. A physician should never allow his name to appear in printed advertisements in recommendation of medicinal preparations.

With regard to the use of phosphorus, Dr. Minot thought he had seen some benefit from its administration in cases of threatened premature senile decay, and also of the so-called "nervous asthenia" in females. In two cases of impotence, one of which was probably the consequence of typho-malarial fever, and had lasted several years, the other without obvious cause, the effect of phosphorus seemed very marked. In both instances a cure followed its use, and each patient subsequently became the father of children. The medicine should be given with caution, and occasionally omitted for a week or two. It should always be suspended when its use is followed by eructations tasting of phosphorus. Dr. Minot had employed pills of one sixtieth of a grain each, one pill to be taken three times daily, after meals, and the dose to be carefully increased.

DR. W. P. BOLLES thought that physicians were more to be censured in this matter than the manufacturers or their agents, since they encouraged by their patronage, often for the most trivial reasons, the manufacture and sale of the class of medicine mentioned by Dr. Edes. This is perhaps more true of those in the country and smaller places than in the large cities. Yet he knew that it was not infrequent in Boston, and mentioned a case where an apothecary, who kept already three or four good manufactures of extract of malt, was obliged by a respectable physician to get another, "because it was put up in such pretty bottles." The agent had just been through the place.

Dr. Bolles advocated favoring such retail pharmacists as could be trusted, and holding them personally responsible for the quality of their medicines, not directing them to get this or that manufacturer's ordinary preparations, nor allowing them to shield themselves behind the names of any wholesale makers, however famous. They should be allowed to make their goods themselves, or buy them where they pleased, but must know that they were all right.

He called attention to the pharmaceutical schools of this country, where young men were well and honestly prepared for business. These graduates, or students, were now to be found in all the medium-sized and larger cities of the Northern States. They would be found, he believed, on the average, to be far better prepared and far more reliable in character than those without the same training, and they certainly had a right to expect the favorable consideration of physicians.

DR. LYMAN thought that if all the physicians in Boston would unite on one good apothecary in each district, to whom people should be sent for their medicines, we might remedy the difficulty. The greatest amount of money which apothecaries took in came from their sale of patent medicines. Prescribing over the counter was objectionable. He thought that if the new law were passed we might perhaps be able to do something.

Dr. BOLLES had found by calculation that the average apothecary got between four and five hundred dollars only per annum from the dispensing of prescriptions, and his opinion was that many of them ought to shut up their shops.

Dr. EDES remarked that it was true, as Dr. Minot had said, that the pharmacopoeia contained forty or more preparations of iron, but he thought, from his recent experience, that if each member of the society were to be asked to name five desirable preparations of iron we should doubtless have the whole list covered. He then read certain objectionable advertisements of medicines in medical journals.

Dr. WARREN said that medical journals depended for their support very largely on advertisements. If they relied on their subscription lists alone, it would be impossible for many of them to continue. It was very difficult to keep questionable advertisements out of a journal, as publishers cannot understand any objection to them, and regard them as so much capital.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

INSTRUMENTAL LABOR, WITH RUPTURE OF THE PERINEUM AND LACERATION OF THE CERVIX; ACUTE CYSTITIS.

MARCH 8, 1879. Dr. WELLINGTON reported the case. The laceration of the cervix extended to the cul-de-sac. During labor there was an unusual protrusion of the anterior lip. Very little is said in the books about cystitis following labor. This case was a severe one. The urine was loaded with pus, the dysuria was great, and the patient suffered intensely. She was delivered ten weeks before, and urination was still painful. The rent in the cervix was in its anterior lip, a little to the right of the median line, and had healed almost completely. The rupture of the perineum was stitched, and good union followed. The cystitis was treated by injections of borax and glycerine, alkalies, and opium. — Dr. LYMAN wished to know if symptoms of cystitis existed prior to labor. — Dr. WELLINGTON replied that there were no marked evidences of cystitis prior to the labor. There was retention of urine for three days after the labor, requiring the catheter. — Dr. LYMAN expressed the opinion that the labor had nothing to do with the occurrence of cystitis; that the cause should be looked for in other directions. — Dr. SINCLAIR reported a case of difficult labor in which repeated and prolonged attempts failed to effect the delivery by the forceps, and which was finally finished by turning. He could not discover the cause of the obstruction. The perineum was ruptured; the cervix was ruptured on the right side up to the cul-de-sac, and slightly so on the left. The vagina was very much injured. The perineum healed very imperfectly. For the acute cystitis which supervened the urine was drawn for fourteen days. Carbolic injections were employed only *per vaginam*. — Dr. LYMAN asked if there had been any trouble with the cervix. — Dr. SINCLAIR replied that he was not aware of any, but after the birth the cervix lay almost without the vulva. The delivery by version was effected without any difficulty whatever. — Dr. LYMAN observed that some twenty-five years ago Dr. McDonnell, of

Montreal, had published several cases in which he had injected the bladder with solutions of nitrate of silver. — Dr. BOARDMAN remarked that the case reminded him of a paper presented about two years ago to this society, in which Dr. Richardson gave the details of a series of cases which, as recollected now, were termed acute cystitis following confinement, and due to actual injury to the bladder from the violence of the labor. Dr. Boardman (present at that meeting as a guest), suggested a cause of the cystitis in those cases, differing from that assigned in the paper, which he would now repeat, as important in connection with the case reported, namely, the partial paralysis of the muscular layer of the bladder, due to prolonged pressure, and giving rise to its incomplete evacuation and the retention and decomposition of a portion of the urine, which he had ventured to call residual urine, and which might readily occasion subacute or even acute cystitis. He had satisfied himself of the fact of this frequent incomplete emptying of the bladder after tedious labors. In regard to the laceration and subsequent union of the cervix, as related in the history of the case, Dr. Boardman desired to call the attention of the members to the fact that this result goes to confirm the remarks he had made at a recent meeting of the society, namely, that antero-posterior lacerations usually unite without treatment, owing to the normal lateral pressure of the vaginal walls, and, further, that, as a general rule, lacerations are more likely to occur in labors with a precipitate second stage. Now cases where the forceps are applied in the high position may be considered as belonging to this category, and, as we might expect, it is the fact, as in the case reported, that lacerations of the cervix are very likely to occur in such cases, a result which has recently been confirmed by the experience at the Rotunda Hospital in Dublin, where the high forceps operation was quite frequently done by the immediate predecessor of the present master. — Dr. FIELD stated his belief that cystitis was dependent upon diseases of other organs, and not upon labor. He had seen a case of irritability of the bladder from an affection at a distant part of the body, and another from hemorrhoids, both of which, when removed, resulted in a cure of the cystitis. He should as soon expect to find the disease in a simple as in a difficult case of labor. As to washing out the bladder, he thought very little could be gained by the procedure in the acute stage, but that it ought to be of advantage in chronic cases. He would suggest, as a treatment of cystitis in women, rest and a liberal diet.

TERATOMA.

Dr. HOSMER reported the case, and exhibited the specimen. The following record is of an autopsy, made June 17, 1878, thirty-four hours after death. The body was that of a colored female, eight months old, and was partially frozen. Emaciation was well marked. From the vagina there had escaped a bloody discharge, considerable in quantity. The base of the chest was broad, and the ribs, by their elevation, were brought so close together that the intercostal spaces were almost obliterated. The umbilicus was prominent, but not large; its relative distance from the ensiform cartilage was a striking fact. The abdomen was full and wide, but quite symmetrical in shape. Its circumference was fifty-two centimetres. Internally, upon the peritoneum, were here and there

some slight patches of injection. A very small quantity of clear liquid had gravitated into the pelvic cavity. The mass of the intestines lay, for the most part, upon the left side. At the points where they had come in contact with the growth, soon to be described, they were adherent, but not firmly so; otherwise they were normal. The growth itself, extending from beneath the liver almost down to the brim of the pelvis, filled the right half of the abdomen. It was attached to the anterior abdominal wall by a pretty large area of adhesion. Its separation from all adjoining parts was effected very easily, and almost entirely with the finger, by a process similar to that of enucleating a fatty tumor from its bed in the cellular tissue. It almost seemed as though its removal during life might have been accomplished with a facility that does not always belong to the operation of ovariectomy. Its firmest connection was with the spine, near the root of the mesentery. Its posterior surface rested against the kidney, and it is therefore to be presumed that it was extra-peritoneal; hence there comes the thought that, through a lateral incision, it might have been taken away without endangering the great serous cavity of the body. The uterus and ovaries presented nothing abnormal. The liver, excepting its dislocation upwards, the kidneys, and the spleen were entirely natural. The diaphragm was highly arched. The chest contained nothing of importance. The head was not examined. The unnatural growth was preserved entire, and transferred at once to the custody of Dr. R. H. Fitz, whose description and explanation of the specimen are as follows:—

The tumor formed a lobulated mass as large as a child's head, and several rounded nodules were attached, the largest the size of an apple. Its weight was more than two pounds. The central mass had a somewhat doughy consistency, and contained parts whose density was that of cartilage; some of the lobes and accessory nodules were evidently due to the circumscribed accumulations of fluid in considerable quantity. The surface of the tumor was covered with a smooth, glistening layer of fibrous tissue containing numerous and large blood-vessels, while several patches of fibrinous false membrane were found adherent. A large cyst upon the anterior face of the tumor, which had been punctured during life, contained a few ounces of opaque yellow (purulent) fluid, and its inner surface was deeply and extensively injected. The wall of this cyst, like that of the others, was separated from the smooth, glistening, fibrous envelope of the entire tumor by a thin layer of fat tissue. There were two sorts of cysts, the one having an external cutaneous wall and thin, watery contents, the other a smooth, glistening, fibrous external surface and glairy contents, in which were opaque gray streaks. Both varieties of cysts were to be found enveloped in a thin fibrous membrane, forming the outer wall of an inclosing sac, though this was not invariably the case. The intervening space was filled with a moderate quantity of desquamated epidermis, resembling the *vernix caseosa*, upon the cutaneous surface referred to, while no contents were found in the space between the envelope and the cyst proper in the second variety. The cysts with glairy contents were presumably of different developmental origin, some having ciliated epithelium upon the inner surface of their wall, while others had a cylindrical epithelium. The glairy fluid gave the reaction of mucine on the addition of acetic acid. One of these cysts, containing

some eight ounces of fluid, communicated by an opening large enough to admit the little finger with a convoluted tube some eight inches in length, resembling a piece of small intestine, and distended with its glairy contents so as to be nearly an inch and a half in diameter. This tube lay within a serous cavity, was attached to a sort of mesentery, and bore a close resemblance to intestine; on its serous surface were several fibrinous patches. A small quantity of dirty-brown fluid, resembling meconium, was to be squeezed from the vicinity of the coiled cyst, though its exact point of origin was not determined. The microscopic examination of a portion of the wall of one of the smaller cysts showed that not only was the surface covered with epithelium, but epithelial pouches extended into the substance of the loose vascular, fibrous tissue of which the inner wall was composed. The cutaneous covering of the first series of cysts referred to contained delicate hairs, and convoluted tubes resembling sweat glands were found beneath the epithelial layer. The solid portion of the tumor was composed mainly of fat tissue. In this were islets of tissue of the most varied sort: bone, with large medullary spaces containing red marrow, hyaline cartilage, bands of dense fibrous tissue, striated muscular fibre, and lastly a finely granular intercellular substance in which were numerous round cells and delicate medullated nerve fibres. The tumor is therefore to be regarded as a teratoma, containing not only tissues from the several germinal layers, but also organs, as the skin and mucous membrane, and even a viscus, namely, the piece of intestine referred to. The cysts lined with ciliated epithelium were not to be considered as belonging to the nervous system, as the epithelium covered a structure more analogous to a mucous membrane than to the ependyma lining the central cavities of the brain and cord.

June 5th, eleven days before death, I made my first visit, and obtained the following clinical history: The child was born at term of a mother whose health had been good throughout her fourth pregnancy. It had always been nursed, though from the age of four months it had received some artificial food. It had thriven tolerably well until the last of May. When it was a month old the abdomen was first thought to be larger than usual, and from that time its size had been steadily increasing. Two days since it was tapped at some institution in Boston, and fluid was obtained to the amount of five hundred cc. Now there is no appetite; some vomiting and diarrhoea; tongue slightly coated, but moist; marked diminution of flesh and strength; sleep seriously interfered with. The temperature, pulse, and respiration are respectively 102.6°, 144, and 60. The quantity of urine is normal. There is slight oedema of the vulva. No teeth have yet appeared, even beneath the gums. The evidence of general discomfort and suffering is abundant. The abdomen is full and broad, symmetrical in shape, firm and resisting on the right side, covered with a net-work of veins which are moderately distended. Its circumference is 57.5 cm. In all positions of the child there is an area of dullness which includes all the right half of the abdomen, and in its lower two thirds encroaches considerably upon the left side, where its limit is nearly parallel with the median line. Under the finger, the outlines of the growth are not very well defined, but its lower portion fluctuates distinctly. After the removal by aspiration of one thousand cc. of turbid fluid, the circumference of the abdomen is re-

duced to fifty-one cm., and the veins disappear to a very large extent. There appears in the lower part of the right hypochondrium a distinct prominence, which gives to the touch the impression of a solid subcutaneous body, two cm. wide and five cm. long, and lying transversely in abdomen. The fluid removed has a density of 1012, is decidedly albuminous, and furnishes a purulent-looking deposit which, under the microscope, is seen to consist of granular corpuscles in which no nucleus is developed upon the addition of acetic acid.

The diagnosis made at this date, excluding ascites, did not advance beyond the recognition of a compound mass, of which the lower portion was cystic and the upper one solid. After this no new symptoms were developed excepting some slight riles in each chest posteriorly. The general description which has been given applies perfectly to the case on any subsequent day. The prognosis became steadily more and more unfavorable. After the aspiration the abdomen began at once to enlarge, and continued to do so until June 15th, when, to relieve its extreme tension, five hundred cc. of fluid were drawn off. This fluid differed from the first specimen only in that it produced a much more abundant, heavy, purulent-looking deposit. Death occurred early the following day, June 16th. The treatment was simple in the extreme, and included nothing of any value beyond the surgical remedy of tapping.

DR. FITZ mentioned the various parts of the body from which these tumors may arise, and remarked upon the very curious point of origin in the present case. In general, the cases have usually been spoken of under the head of "fetus by inclusion." The specimen exhibited was the most curious that had occurred in this vicinity. In a similar tumor removed from the neck by Dr. Hodges, a few years ago, there was merely a combination of tissues without any resemblance to a particular organ.

THE ANTIQUITY OF INTRA-UTERINE INJECTIONS.

DR. HOSMER exhibited a work on midwifery published in London in 1769, written by Dr. Robert Wallace Johnson. Among the plates is one presenting a section of the uterus and whole pelvic region, and showing the syringe in position for an intra-uterine injection.

Recent Literature.

A Treatise on the Science and Practice of Midwifery. By W. S. PLAYFAIR. Third American Edition. Philadelphia: H. C. Lea. Pp. 655.

In this edition the author has endeavored to revise the work, with a special reference to American practitioners. The number of changes is not great, and they relate chiefly to matters which are still *sub judice*. We are glad to see that less value is placed on the so-called true corpus luteum as a sign of pregnancy, and that the claims of Dr. Wright as the first advocate of bimannal version for the performance of cephalic version are at last recognized, although the author still claims credit for Dr. Hicks as the one who first showed the possibility of effecting complete version by this means in all cases. A detailed account of Porro's operation, and also of laparo-elytrotomy, has been

added. Many valuable changes have been made in the chapter on puerperal septicæmia. We regret that the author should still so briefly allude to irregular uterine contractions as an agent in producing dystocia, thus entirely ignoring the results reached by Bandl, Martin, and others.

We are also at a loss to understand the reasons for the substitution of the word "pruritis" for pruritus in the paragraph on that disease of pregnancy (page 206). Such a change is warranted neither by the derivation of the word nor in its use by dermatologists.

As a whole, this edition is an improvement on the last, which we have already favorably spoken of in this journal.

The Theory and Practice of Medicine. By FREDERICK T. ROBERTS, M. D., B. Sc., F. R. C. P., etc., etc. With illustrations. Third American from the fourth London edition. Philadelphia: Lindsay and Blakiston. 1880.

The early appearance of another edition of this book is an indication of the favor with which it is received. The addition of some illustrations, which, though not profuse, are well chosen, increases its value. The chapters relating to the absorbent system and the nervous system have been especially revised and extended. We again heartily recommend it to students, teachers, and practitioners.

First Lines of Therapeutics as Based on the Modes and the Processes of Healing, as Occurring spontaneously in Disease; and on the Modes and the Processes of Dying as Resulting naturally from Disease. In a Series of Lectures by ALEXANDER HARVEY, M. A., M. D. (Edin.). Emeritus Professor of Materia Medica in the University of Aberdeen, etc., etc. New York: D. Appleton & Co. 1879.

THESE lectures, as the title-page indicates and as the preface informs the reader, are designed to illustrate, on the one hand, the workings of the *vis medicatrix nature*, or the modes and processes of healing and recovery as occurring spontaneously in disease, and, on the other, the modes of fatal termination of diseases. These two subjects, the author justly remarks, underlie the whole science of therapeutics, and he thinks instruction in them is greatly neglected. If so, our author has made a vigorous effort to repair such past neglect. He worries and shakes his subject until there is no life in it. Sir Thomas Watson, in writing to him of the book, assures him that he has "thoroughly thrashed out the great theme which he proposed to discuss." This the author has done, but it strikes us that a good deal of superfluous energy has been expended in belaboring the chaff after the extraction of the wheat.

— An English physician, having been unable to reach a fatal case in time to render assistance, was "branded by the intelligent twelve (the jury) and their chief," says the *Medical Press and Circular*, "in terms of most unmitigated reproof." This journal further remarks, "Many of the coroners now in office are eminently unfitted to discharge its proper functions."

Medical and Surgical Journal.

THURSDAY, JANUARY 15, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, OSGOOD AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, OSGOOD AND COMPANY, Boston, Mass.

THE SECOND MEDICAL VOLUME OF THE MEDICAL AND SURGICAL HISTORY OF THE WAR OF THE REBELLION.

THIS volume, being the first of Part Second of the medical and surgical history of our late civil war, prepared under the direction of Surgeon-General Barnes by Surgeon J. J. Woodward, of the United States Army, treats of the alvine fluxes, which term embraces acute and chronic diarrhoea and dysentery, and is a mine of information in regard to those diseases. "These disorders," the author tells us, "occurred with more frequency and produced more sickness and mortality than any other form of disease. They made their appearance at the very beginning of the war, not unfrequently prevailing in new regiments before their organization was complete, and although comparatively mild at first were not long in acquiring a formidable character. Soon no army could move without leaving behind it a host of the victims. They crowded the ambulance trains, the railroad cars, the steamboats. In the general hospitals they were often more numerous than the sick from all other diseases, and rivaled the wounded in multitude. They abounded in the convalescent camps, and formed a large proportion of those discharged the service for disability. The majority of our men who were so unfortunate as to fall into the hands of the enemy suffered from these affections. Finally, for many months after the cessation of the war, and after the greater portion of the troops had returned to their homes, deaths from chronic diarrhoea and dysentery contracted in the service continued to be of frequent occurrence among them." And every civil practitioner would mention in this connection the many cases in which these diseases still keep their hold upon their victims nearly fourteen years after the close of the war. It was at first proposed to include the camp fevers in this volume, but the wealth of material in regard to the present subjects made it necessary to postpone them to a third and final volume of the medical history. The author explains and justifies his determination to devote an entire volume of nearly nine hundred pages to diarrhoea and dysentery. He says: "Not only do the alvine fluxes usually cause more sickness and mortality among troops during war than any other group of diseases, but this circumstance affords a better opportunity for their study than can commonly be obtained in times of peace, so that it has heretofore happened that many of the most important accounts of these disorders, whether in ancient or modern times, have been the fruit of

military experience. When I came to study carefully the documents and pathological specimens relating to this subject which had been collected by the industry of our medical officers during the civil war, I formed the opinion that they were well worthy of presentation in detail; and when I began the task of interpreting them by the aid of previous experience I was led to believe that the time had arrived when modern observations might profitably be contrasted with the records of the past, and the historical basis of the dominant opinions of the present day be subjected to careful and critical scrutiny. This I have not hesitated to attempt. The great medical library which my colleague, Surgeon J. S. Billings, has been enabled, by the liberal policy of the surgeon-general of the army and the annual appropriations of Congress, to collect for the benefit of medical officers and of the medical profession of the country has afforded me opportunities for the study of the ancient and modern literature of the subject not heretofore enjoyed by any American medical student, and I have endeavored to make the best use I could of the resources at my disposal." Of the value and success of this attempt any one studying the copious foot-notes, in which the authorities consulted—and few have escaped—are not only cited, but quoted, would be soon convinced.

The number of deaths from diarrhoea and dysentery in the Federal armies during the war is estimated at 57,265, and even this, for reasons indicated, is regarded as less than the actual mortality from these diseases. "The number taken on sick report with these diseases was to the total of all diseases reported about as one to every three and one half for the white troops, and as one to every four for the colored troops. The number of deaths from them recorded in the tables constitute about the same proportion of the whole number of deaths from disease, namely, one to three and one half among the white, one to four among the colored, troops. These rates must be regarded as understating rather than exaggerating the proportion of deaths due to diarrhoea and dysentery."

The number of soldiers discharged from the service on account of disability from these diseases it has only been possible to estimate in a purely approximate degree. As an example of one element of confusion we may mention the large number of certificates of discharge for "debility," namely, 15,040, and again the "many thousands of diarrhoeal patients, sick in the general hospitals, who were mustered out of service at the close of the war." The proportion of acute to chronic cases of diarrhoea among white troops is given as six of the former to one of the latter, and of dysentery as nine of the former to one of the latter; for colored troops, as nine of acute cases of each of the diseases to one of chronic; but these proportions are also subject to some disturbing elements. For white troops there was, according to the tabular statement, one death to every 395 cases of acute diarrhoea; one to every 57 cases of acute dysentery; one to every six of chronic diarrhoea; and one to every eight of chronic dysentery. For colored troops, one

death to every 83 cases of acute diarrhœa; one to every 17 of acute dysentery; one to every four of chronic diarrhœa; and one to every four and one half of chronic dysentery. In regard to these tables, we are informed that numerous records of post-mortem examinations show that the lesions in the cases reported as chronic diarrhœa were identical with those observed in the cases reported as chronic dysentery.

The severity of these diseases increased as the war progressed; they were more frequent and fatal among the troops in the central region, less so in the Atlantic, and least in the Pacific region; they were more frequent, both among the white and colored troops, and in all these regions, during the summer and autumn. Seven thousand three hundred and fifty-two cases of these diseases among the Federal prisoners are recorded on the hospital register of the Andersonville prison, with 5605 deaths, and this does not represent all.

In the summing up of the first section of this volume it is remarked that "our experience in regard to these affections during the war of the rebellion was very similar to what has been recorded of other armies in time of war, and particularly to what has invariably occurred during former wars in the United States."

From the fourth section on treatment, though containing much of interest and value, we have room for but one extract. In regard to the use of opiates in these diseases, we are told, "That they are often appealed to in vain is soon learned by the hospital physician, who will generally find that the majority of cases of dysentery and severe diarrhœa that come under his observation were treated at the start in this way. It is well worthy of inquiry whether the proportion of serious cases is not greater when opiates are freely resorted to at the commencement of what appear to be trivial diarrhœas than when other measures are relied on. I confess, the more I learn of the behavior of such cases under treatment, the more I am inclined to advise that opiates should be as far as possible avoided." Bismuth is recommended in painless diarrhœas after the use of evacuates and in chronic fluxes, and large doses are favored.

We must permit ourselves at least to allude to the great beauty of the plates, and of the photo-micrographs of microscopical sections of the intestine, by Dr. Woodward, which, we believe, were at the Centennial Exhibition in Philadelphia.

This volume, no less than its predecessors, reflects the highest credit upon the department and upon its compiler, and is at the same time a very handsome tribute to the worth of the great Medical Library in Washington.

MEDICAL NOTES.

— G. A. N., aged twenty years, mechanic, of St. Johnsbury, Vt., desired to have several teeth extracted. He was examined by a competent physician, and his heart and lungs were found in good condition. On Friday, December 26th, the patient for one hour inhaled sulphuric ether without the desired

effect. On Tuesday, December 30th, chloroform was inhaled from a napkin within a paper tunnel. Pulse 80, and regular; action of heart and lungs good. Patient soon went kindly under the influence of the vapor; one tooth was extracted; sensibility partially returned; the mouth was cleaned; more chloroform was administered; two teeth were extracted; sensibility again partially returned; another tooth was extracted *without* more chloroform. The patient then began to struggle, and exhibit signs of pain; his head was brought forward, and his mouth well cleared. He was then returned to his former position, when he suddenly threw up his arms, rolled up his eyes, and ceased to breathe. He was then instantly placed in an inverted position, his tongue drawn forward, and artificial respiration applied. The heart still continued beating, yet there was no pulsation at the wrist; face very livid, and no natural respiration. The heart continued to act very feebly and irregularly until forty-five minutes after breathing ceased. Efforts were continued until, at the end of one hour, the patient was pronounced dead. Artificial respiration, inversion of body, electricity, iced water, and all other known remedies were faithfully employed. Amount of chloroform used three ounces by weight. No post mortem.

— The disease among cattle in Haverhill, N. H., has been pronounced to be pleuro-pneumonia, of a non-contagious character, by Dr. Thayer, of Massachusetts.

— It can hardly be considered a compliment that a journal so intelligent as the *Medical Press and Circular* is so unfamiliar with the medical department of the Harvard University as to speak of it as the "Massachusetts Medical School, Boston, United States." Such mention, however, occurs in an allusion to the fact that the late Mr. Callender was to have spoken at the opening exercises of the school in October last. Readers of the *Press and Circular* may well have thought that the medical department of the Boston University (a homœopathic institution) was the school in question.

— A new journal, devoted to the diseases of children, under the name of *Archiv für Kinderheilkunde*, is announced to appear in Germany. Drs. Baginsky, of Berlin, and Herz and Monti, of Vienna, are to be its managers.

— At Cambridge, England, a lady is acting under the direction of Dr. Michael Foster and Mr. Balfour, as demonstrator to the students who are studying physiology and comparative anatomy under the auspices of the Association for the higher education of women. Irrespective of the entries at Girton College, eighty-two ladies are now attending the lectures at Cambridge which have been arranged for the sex, and a large number are formally engaged in the study of natural science.

— The *Canada Lancet* reports the death of a lady from ether, administered by a physician for the purpose of extracting a tooth. Scarcely an ounce had been used. Coroner's verdict: Paralysis of the heart, caused by inhalation of ether.

— It may not generally be known that the theatrical expression, "a beggarly account of empty boxes," is not only Shakespearean, but semi-medical, in origin. It occurs in Romeo's description of the "needy shop" of an apothecary: —

"And about his shelves
A beggarly account of empty boxes,
Green earthen pots, bladders, and musty seeds,
Remnants of packthread and old cakes of roses,
Were thinly scatter'd to make up a shew."

— According to the *Apotheker-Zeitung*, says *New Remedies*, out of 118 samples of toys officially examined in 1878, nearly one half (53) were adorned with poisonous colors. The vendors were punished in forty-six cases.

— Some of our best medical journals have adopted the scandalous practice of sandwiching advertisements between the pages of medical essays. This is not only undignified, but is an unmitigated nuisance.

— A. H. Crosby, M. D., Concord, N. H., and H. P. Watson, M. D., Haverhill, N. H., have been appointed as the medical men upon the commission to examine a herd of cattle in Haverhill, supposed to be affected with pleuro-pneumonia.

— An able reviewer of the *New Orleans Journal* makes the following sensible remarks on a series of lectures, by Dr. Jones, entitled *The Grounds of a Homœopath's Faith*. The book having been sent us for notice, we do not think we can do better than quote the words of the writer referred to: "The lectures are upon the following subjects: I. The Law of Similars: Its Claim to be a Science in that it enables Prevision. II. The Single Remedy a Necessity of Science. III. The Minimum Dose an Inevitable Sequence. The above title is eminently appropriate, inasmuch as homœopathy is based wholly on faith, and is in reality a religion rather than a science. The *prevision* claimed as one of its achievements is another word for prophecy, which is *par excellence* a sacred gift, not claimed by any scientist. The distinctive attribute of the homœopath is declared to be 'not the law of cure, not the infinitesimal dose, not the Hahnemannian hypothesis of chronic diseases: none of these, but simply this,—his fixed faith in the efficiency of drugs.' Another evidence of the religious character of homœopathy is the reverence felt for the author of the system by his followers, amounting to a belief in his infallibility and perfection quite akin to the homage paid to Moses, Mohammed, and Joseph Smith. The great lights in medicine are more or less honored in their day; but their authority cannot stay the onward march of science, and they are left as monuments of the past. This is a land and an age of religious toleration, and no one should forbid the name of Hahnemann to be glorified, or scoff at the faith of his followers in the mysterious potency of the thirtieth dilution of gun-flint or common salt. To many minds such faith is not only a comfort, but a necessity. Distrustful of their own knowledge and understanding, they seek refuge in the mysterious and incomprehensible rather than trust science in its acknowledged imperfections. Yet, with all its absurdities, homœopathy is not the worst form

of idolatry. True, lives are sacrificed in its blind following; but the fittest survive in this mode of selection, and the race becomes improved, as it certainly must by the ravages of small-pox and other diseases made avoidable by enlightenment and prudence. In the second lecture the single remedy is set up as the perfection of therapeutics, while noting the gradual progress from polypharmacy to simplicity in the history of medicine. One point, however, needs explanation for our unregenerate comprehension, and that is the invariable resort to alternate doses from two different remedies. Perhaps this is another mystery of the system, incomprehensible, and therefore sacred; perhaps it was suggested by antiphonal modes of worship, as practiced in other religious rites.

"The last lecture traces a gradual diminution in dosage among medical men, but fails in establishing a connection with the infinitesimals of homœopaths. The potency developed by progressive dilution is probably one of the most sacred mysteries of the whole system, and undoubtedly the most awful in sublimity. Being incompatible with the established and understood properties of matter, this astonishing capacity of multiplying force by division of substance becomes a veritable miracle, and ranks with the doctrine of transubstantiation.

"The grammar and rhetoric of Dr. Jones are unimpeachable; the mechanical work of the little volume is excellent. In flexible binding, with Faith as its title-word, and its three chapters joined in one volume, it is peculiarly adapted for a manual to aid in propagating the gospel of Hahnemann."

— Rudolph claims that an acute case of coryza may be cut short within an hour by chewing one or two dried leaves of the eucalyptus, and swallowing the exceedingly bitter and aromatic saliva. In chronic cases no such effect is produced.

— According to the *Western Lancet*, a woman was listening to a telephonic message when a violent clap of thunder was conveyed by the wire to her ear. The effect was complete deafness, with numbness, tinnitus aurium, slight nausea, and a sensation of giddiness. These indications of a concussion of the auditory nerve passed off in a few days.

— In the *Pharmacy Journal*, W. B. Paul says the simplest and easiest method of detaching leeches is to let fall a few drops of camphor water upon the part.

— Professor Yandell writes to the *Louisville Medical News* from London that "getting into practice is here, as elsewhere, slow work; and, while merit is probably the best means of securing a business, manners and machinations, the Sunday-school and church dodge, and the total abstinence game and judicious lying about skill and success, and stealing other men's ideas and putting them in print, are roads to prosperity no more neglected here than in our own enterprising country."

— Says the *Medical Press and Circular*, "A joiner named M'George died at Liverpool on July 14th. The post mortem indicated apoplexy. The man had eaten some lettuce for his tea the night before; the

doctor had probably heard of lettuce-opium, and actually swore that the apoplexy had been induced by the quantity of lettuce, which would be dangerous to an elderly person! The jury found that death had resulted from poison (!), but whether or not it was contained in the lettuce there was not sufficient evidence to show!"

Apparently the grave-digger in Hamlet had more wit than the average English coroner of to-day.

— Stains caused by nitrate of silver may be removed simply by wetting the stain or mark in a solution of bichromate of mercury.

— This criticism on a modern fashion is from the *Medical Press and Circular*: "Medical men have, during the last few years, found a lucrative field for literary work in our high-class monthlies and quarterlies. Medical subjects are interesting. We have received some letters on this subject. If Dr. Great-Gun is allowed to write an article in the *Nineteenth Century*, on some medical subject, and to append his name, why should not Dr. Small-Gun write to the *Village Gazette*, and sign his name to some medical paper? What an advertisement it would be for him! But an outcry would be at once raised against such a procedure by the local professional men. There does not seem, at first sight, to be any flagrant violation of professional customs in writing for lay journals. There is this danger: It may be abused, and become another method of indirect public advertising."

— We find the following in an English medical journal, as noticed by us a year ago:—

"The State Board of Health for Massachusetts, in their tenth annual report, direct the attention of the state legislature to the experience of Illinois, where, in one year and a half, fourteen hundred self-styled doctors are reported as having left the State, because they were unable to pass the examinations required of them. Of these, four hundred are estimated to have gone to Indiana, two hundred and fifty to Wisconsin, one hundred to Minnesota, and an unestimated number to Missouri."

A similar censorship would be a needed boon to our own city and State. Legislation in the same direction is contemplated in Great Britain. In France there is a definite law on the subject, namely:—

"ART. 35. Six months after the publication of the present law, any person who shall continue to practice medicine or surgery, or to act as accoucheur, without being on the list of those qualified to do so, will be liable to a fine, to be handed over to an almshouse."

"ART. 36. Notice of such offense should be given to the tribunal of Correctional Police, and to the notice of the government commissioner (solicitor of the republic to these tribunals). A fine of one thousand francs may be imposed on any person who shall take the title of doctor, or practice as such."

"A fine of five hundred francs may be imposed on any person who shall take the title of licentiate and visit the sick as such."

"In case of relapse, the fine shall be doubled, and the delinquent shall be liable to an imprisonment, not exceeding six months."

— A new medical school — the College of Physicians and Surgeons — has recently been organized in St. Louis. It begins with a preliminary examination and engages to exact a high degree of scholarship.

PROVIDENCE.

— The death of a patient while under the influence of ether occurred in this city on the 17th ult., under the following circumstances: The patient, a man aged about fifty-five years, was knocked down by a runaway horse, and sustained some injury about the hip. The next day sulphuric ether was administered to facilitate the diagnosis, and after taking it for about fifteen minutes the man, without any warning, ceased to breathe. Artificial respiration was resorted to, but without success. The autopsy showed effusion of serum beneath the arachnoid, with thickening of that membrane, valvular lesions of the heart, and cystic degeneration of the kidneys.

— Scarlatina still prevails to an alarming extent, the deaths from this disease in December numbering 71 out of a total mortality of 213. This number is far in excess of any previously recorded in this city, and exceeds by 16 the number of deaths from this cause during the whole of the year 1878. The plan recently inaugurated by the superintendent of health of requiring physicians to report all cases of contagious and infectious disease, is working very satisfactorily, and is showing much more correctly the prevalence of those diseases and the localities in which they originate than the old method of reporting deaths only. It is anticipated that some very valuable statistical and sanitary results will be thus obtained.

NEW YORK.

— At a stated meeting of the New York Neurological Society, of which J. C. Shaw, M. D., is president, and William J. Morton, M. D., secretary, on Tuesday evening, January 6th, there was a discussion on Dr. Shaffer's paper (read at the last meeting), and the presentation of the report of the committee on asylum abuses, entitled, An Answer to the Document known as the Report of the Committee on Public Health relative to Lunatic Asylums.

— On the 31st of October last diplomas conferring crosses of merit and knighthood in three German princely orders were presented at St. John's Hospital, Beirut, Syria, to Drs. Van Dyck, Wortabet, and Post, who constitute the medical staff of the hospital. Dr. Van Dyck was decorated with the Prussian Order of the Crown, Dr. Wortabet with the golden cross of merit of the Order of the Grand Dukes of Mecklenburg, and Dr. Post with the cross of the Knights of the Order of the Dukes of Saxony. Dr. Post, who has won great distinction throughout Syria and the Levant, is a son of the venerable Professor Alfred E. Post, of New York, and Dr. Van Dyck, who is well known as an eminent Oriental scholar, is also an American.

— The whole amount recently contributed on Hospital Saturday and Sunday has not yet been announced by the committee, but it will no doubt be a

very handsome sum, as the response to the call was very general and hearty. Besides Mr. Wm. H. Vanderbilt, it is said that the firm of Drexel, Morgan, & Co., Mrs. A. T. Stewart, Judge Hilton, and others contributed a thousand dollars each.

—The sanitary superintendent, Dr. W. De Forest Day, has handed in to the board of health a table giving the number of cases of the various contagious diseases reported during each month of the year that has just closed. From it we learn the following facts:—

But eight cases of typhus fever were reported during the year, of which four occurred in August and four in September. There was an average of thirty-six cases of typhoid fever reported each month, the largest number (seventy-four) occurring in September, and the smallest number in March (nineteen). Sixty-five cases of small-pox were reported, of which the largest number occurred in June and July, thirty-one in the former month and thirteen in the latter. Since July there has been but one case reported, and that was in November. Cerebro-spinal meningitis was rather more prevalent during the summer months than at the beginning or ending of the year, the largest number of cases (eighteen) being reported in August, and the smallest (four) in December. Diphtheria, on the contrary, was less common in August than in any other month. It gradually diminished from 268 reported cases during January to 79 during August, after which the cases slowly increased again until they reached 203 during September. The most prevalent of all the contagious diseases during the year, however, were scarlatina and measles. The former was epidemic at the commencement of the year, 986 cases being reported in January alone. After this it decreased with a pretty regular gradation until November, when its minimum was reached, 136 cases. During December the number increased to 201. The course of the measles was less uniform. In January but fifteen cases were reported. It then slowly increased until April, when the number jumped up to 122, after which it increased with a more regular progression until July, when 223 cases were reported. It now fluctuated, sometimes diminishing and sometimes increasing, until December, when there was a very marked increase again, the number of reported cases reaching the unusually large figure of 974. Since the beginning of the year, however, the disease has become less prevalent again, and the month of January will probably not show nearly as many cases as December did. The totals for the various diseases during the year are as follows:—

Typhus fever	8 cases.
Small-pox	65 "
Cerebro-spinal meningitis	107 "
Typhoid fever	433 "
Diphtheria	1784 "
Measles	2424 "
Scarlatina	5447 "

—On the 7th of January the Board of Apportionment appropriated \$130,000 from the excise funds for the various benevolent institutions of the city. This, together with more than a million and a quar-

ter for the Department of Charities and Correction (which includes Bellevue Hospital and the institutions on Blackwell's, Ward's, and Randal's islands), and still another million for additional "asylums, reformatories, and charitable institutions," makes a grand total of about two and a half million dollars to be expended during the year for charitable purposes from the public funds, in addition to perhaps as much more bestowed upon similar objects from private sources.

—At the last meeting of the County Medical Society, December 22d, Dr. John S. Billings, U. S. A., read a valuable paper on The Organization and Operations of the National Board of Health.

—The Improved Dwellings Association, which was organized some months ago for the purpose of erecting properly constructed tenement houses for the poorer classes, has bought a large piece of land, consisting of twenty-one lots, in the upper part of the city, near the East River. The buildings that will be erected on this property will constitute the largest and most complete set of improved tenement houses yet put up in New York, and every effort will be made by the association, which consists of a number of enlightened and philanthropic capitalists, to secure the best possible arrangements for ventilation, light, drainage, and other sanitary requirements, as well as the general comfort and welfare of the occupants. The association is also now looking for a suitable piece of land down town, in some thickly settled district, upon which to erect another set of buildings of similar character.

—At the last meeting of the Medico-Legal Society, January 7th, Dr. John C. Peters read the report of a special committee on the subject of hanging, of which he was chairman. The committee, he said, were unanimously in favor of capital punishment for murder, and believed that hanging, when properly conducted, was a satisfactory method of execution, being quick, merciful, and sufficiently ignominious. The committee did not recommend any special mode of hanging, but thought it should be so managed that death should take place within two minutes. Five minutes was regarded as quite too long a time, and fifteen minutes altogether unjustifiable. Dr. Houghton, of Dublin, who was formerly a clergyman, had devoted considerable study to this subject, and he was in favor of a knot under the chin, instead of at the side of the neck. The knot arranged in this manner would, he believed, cause strangulation and suffocation in the shortest time, and the head being thrown up by the drop there was also a great probability of the neck being dislocated. He advocated in connection with this a long drop, from ten to fourteen feet instead of five.

—Dr. David L. Eigenbrodt, who died in this city on the 3d of January, was born at Jamaica, Long Island, in 1811, and after pursuing his medical studies under the direction of the late J. Kearney Rodgers, then one of the most prominent New York surgeons, was graduated at the College of Physicians and Surgeons in 1835. The year previous to this he had

served as an *interne* at Bellevue Hospital during the noted cholera epidemic of that time, and for the faithful and courageous performance of his duties was presented with a case of surgical instruments by the almshouse commissioners. Three years after receiving his degree he went to Cuba, where he remained for fifteen years in active practice, and acquired a competence. In 1852 he returned to New York, and there became the first resident physician at St. Luke's Hospital. This position he retained for two years, when he relinquished it to take the post of house-surgeon in the old New York Hospital. After serving in this capacity for one year, he abandoned medicine as a profession, and retired to private life. He still continued to practice gratuitously among the poor to some extent, however, and he was also very liberal in his donations to charitable objects. Although retired and unassuming in his manners and tastes, he was of a very genial disposition, and was much beloved by a large circle of friends. His last illness was a lingering one.

LONDON.

—A correspondent writes to us from London, under date of December 11th, as follows, in regard to a lecture delivered by Sir Henry Thompson: "Speaking of the size of the urethra and the detection of a stricture at any point, he said that he did not deny the fact that the urethra was much more capacious than was formerly supposed; but he did wish to say that it was unnecessary and wrong, in examining a patient, to pass a larger instrument than a No. 10-12 (English), as with that the practiced hand could detect a stricture as well as with a No. 16 or 17. . . . I accepted an invitation to attend the debate on Antiseptic Surgery at St. Thomas's Hospital. The speakers were all in favor of Listerism, with the exception of Mr. Bryant, who made quite a savage attack on Mr. Lister and his followers, accusing him of withholding statistics, and claiming as good, or even better, results for other methods. Professor Nussbaum's article on Antiseptic Surgery was referred to and discussed at some length. There was also shown for the first time some soluble drainage tubes made from decalcified bone, as used by Es-march.

"The two operations spoken most highly of by surgeons of the Lister school just now are wiring the fragments together in old or recent fractures of the patella, and the operation for genu valgum by the division of the inner condyle of the femur, both of which have been performed several times, and invariably with good results. In one of the cases of wiring the patella by Mr. Bell, of King's College Hospital, the fragments were separated about two and a half inches, and so bound down by adhesions that it was found necessary to divide the rectus muscle, which was accordingly cut through subcutaneously down to the femur, and a drainage tube put into the cut. Lister's dressing was applied, and the temperature only once reached 100°. The patient recovered perfectly, with a good patella and a movable joint. The one thing that has struck me most forcibly is the appar-

ently reckless manner in which London surgeons who follow Lister open the knee-joint. It seems to me that there are more precautions taken here than with us as regards towels, etc., that have not been carbolicized touching the wounds, and more 1 to 20 carbolic is used in washing, etc. . . . Almost every one mentions Dr. Bigelow's operation for stone, and speaks very highly of it."

Correspondence.

LETTER FROM PHILADELPHIA.

MR. EDITOR.—Phenomenal weather is always considered a legitimate topic for discussion, although one that quickly loses the charm of novelty. It is worth remarking, however, that, while on the western shore of the continent the weather was reported to be so cold during the holidays as to be almost unprecedented in San Francisco annals, the "spell" that we have been treated to in Philadelphia has been one of unusual mildness; thus far it has been for the most part a real Southern winter. Indeed, upon some of the sunny days one could well imagine himself upon the shores of the Mediterranean; the warm, bright atmosphere involuntarily suggesting the thought that a beneficent Providence had brought Italy to the invalids in their own homes, — a genuine case of mountain come to Mahomet, for the benefit of those who could not get away.

Seasonable weather is always healthy, — at least so say the sanitarians; and while vital statistics show that both extreme cold and extreme heat tend to increase the mortality, we also observe that a warm, damp winter and a cold, damp summer equally exert an unfavorable effect on the public health. Influenza is now very prevalent, and bronchitis and pneumonia are common. In two of our large hospitals, where zymotic disease had in one never previously existed, and in the other had been banished from the surgical wards for more than five years, a limited outbreak of erysipelas occurred among the recent amputations and others, so that one surgeon at least considered it advisable to postpone all cutting operations until the weather became more settled. In connection with this we notice that after an entire immunity from small-pox for over two years we have had several deaths from it during the last few months, from one to four per week appearing in the returns. Prompt measures have been taken by the board of health to look after these cases and isolate them and disinfect the premises, so that no fears whatever are entertained of an epidemic. Typhus fever is stated, on the authority of Professor Pepper, to have made its appearance in the Philadelphia Hospital. We note that a committee of the health board have been examining the hay used to cover the floor of the city horse-cars during the winter months, and report that it has been heretofore allowed to remain indefinitely, fresh hay being sometimes put on top to cover the fermenting, sodden mass below. They therefore denounce the practice, considering the hay a good nidus for zymotic disease, and declare its exhalations prejudicial to public health. One of the lines (Fairmount Avenue) has already discontinued the use of hay as a foot-warmer for passengers, and has introduced small stoves in the front part of the car, which answer all purposes.

The efficient health officer, Mr. John E. Addicks, presented a report to the board of health, in which he gave the following account of an outbreak of small-pox, and the measures he had successfully pursued in arresting the epidemic:—

"After an immunity of more than two years from small-pox and varioloid,—the last death was reported August 13, 1877,—on the 23d of November I received report of a case of small-pox at No. 2809 Rosehill Street, twenty-fifth ward, a boy of seven years of age. On special examination the report was verified; the patient, Francis G., died on the 26th of November. In the same house a brother of twenty-one years had varioloid.

"The origin of the disease was traced to a boy in the same family, who, in the early part of November, had a slight pustular eruption of so mild a character that he continued to attend the public school. A few days afterwards three more children in the same family and house, respectively nine, twelve, and fourteen years old, were attacked in an equally mild form; the next patients in the same family were the two well-defined cases reported to me under date of November 23d, and received on November 25th.

"Prompt steps were at once taken by me, the facts stated by your president, and a special meeting of the board was held, which gave me full power and discretion in the whole matter. In obedience to my instructions, I advertised in the newspapers that physicians must make prompt return of all contagious diseases in the children of the public schools of the district. Of the latter order I advised the president of the Board of Public Education. I directed all families having small-pox or varioloid at home to keep their children from attending school or other places of public resort; in case of death, burial to take place promptly without funeral, and advise at this office at once, so that all bedding, clothing, etc., might be disinfected.

"I appointed Inspectors Cunningham and McBride a special commission to make domiciliary visits throughout the whole district, inspect every part of each household, give forthwith notice to abate any nuisances found, and make daily reports. I organized two gangs of workmen under direction of the above-named inspectors to abate any nuisance found not attended to within twenty-four hours after inspection and due notice. Directed the chief inspector of streets to have the whole section thoroughly cleaned and kept so. All of the above has been promptly attended to, with most beneficial results, and, as you will find by annexed tables, the disease at this time is most certainly checked, but not entirely eradicated."

The following statistics of the mortality of the city during 1879 were obtained from the health office, which, with the weekly reports of mortality published in each number of this JOURNAL, will supply some useful information to those interested in public health. The rate for the year was about 18 per 1000, based upon the estimated population in July, 1879 (301,380), which, however, is decidedly below the number in the winter months; the ratio should therefore be between 17 and 18 per 1000. From the reports of the past year it appears there was a total number of deaths in this city of 16,281. During the year 1878 the deaths were 15,743; in 1876 there were 18,892 deaths; in 1875, 17,805; and in 1874, 16,315. The month of 1879 when the most deaths occurred was July, when

they reached 1885, while the lowest was June, during which there were but 1006.

There have been several cases before the courts recently, in which reputable physicians have been caused considerable annoyance by the persecutions of persons who, having been pronounced insane and sent to a hospital, have subsequently escaped and entered suit for conspiracy. The latest case of the kind is one in which Drs. Edward H. Smith and George C. Harlan have been sued by a patient, damages being laid at \$50,000. After a commissioner in lunacy had examined the man and pronounced him insane, another commission was appointed, which disagreed. Subsequently Drs. Harlan and Smith were called in, and, being satisfied of his insanity, made out a certificate in due form, and his friends took him to the Pennsylvania Hospital, from whence he was released by an order from the court. This case will be watched with much interest not only by the respondents, but by other physicians. In the mean time we are having an epidemic of vitriol-throwing, shooting, and other extravagant and eccentric manifestations; but, however much of a lunatic a man may be, it is at present difficult to get a physician to sign a certificate. It is now recommended that when the friends want a physician to examine an insane patient they shall first sign an indemnity bond for \$20,000, guaranteeing to protect the physician from any future annoyance in the case. It is needless to say that the newspapers, generally, have improved the opportunity of calling attention to the delinquencies of physicians, and lecturing the profession for its venality and carelessness; for your newspaper man, as a rule, has little respect for a physician, unless he advertise liberally in the journals.

The medical schools, both the University of Pennsylvania and Jefferson College, have large classes in attendance; and there will apparently be but little falling off, if any, in the number of the graduates this commencement from those of last year.

The medical societies are thriving, have generally interesting meetings, and are well attended. The last three meetings of the Obstetrical Society have been devoted to the discussion of hour-glass contraction during the second stage of labor, which Dr. A. H. Smith, who opened the debate, contended had no existence, at least as this pathological state is popularly understood. Some very interesting cases of this condition, however, were cited; notably, one by Dr. J. F. Wilson, in a case of twins, where, one being delivered, the second, inclosed in a separate sac, was prevented from descending by a falciform contraction of the body of the uterus, the os remaining perfectly patulous.

At the last meeting of the College of Physicians, Dr. Robert P. Harris read a most interesting paper on Foot-Binding in China, giving an account of the process and its effects, and correcting many erroneous statements which have been made, chiefly by travelers, in regard to it, and giving a reference to cases of gangrene produced from tight bandaging for this purpose.

Among the interesting cases presented to the Pathological Society recently might be mentioned a case of primary medullary carcinoma of the bladder, by Dr. James Hearn, in which hæmaturia, pain, and emaciation were marked symptoms.

The County Medical Society has just issued its first volume of proceedings for the last year, which contains a number of papers of permanent value and interesting discussions; also a full list of the members

and officers of the society. The audiphone was lately presented by Drs. Charles Turnbull and Charles H. Thomas, who were subsequently appointed a committee to investigate the subject further. The principle of enabling partially deaf persons to hear by means of vibrations conveyed to the cranial bones is not new, but the general application is novel and valuable. A multitude of materials may be made use of in constructing an audiphone, which is merely a large disk, held by a handle like a fan against the teeth, to which it communicates sonorous atmospheric vibrations. A fuller report of this ingenious instrument, and instructions for constructing a substitute which will answer every purpose, will appear shortly in this journal in another column. By invitation of the society, Professor Joseph P. Remington, of the College of Pharmacy, read at an adjourned meeting, held December 29, 1879, a valuable and instructive paper on The Metric System in Medicine and Pharmacy, a copy of which was requested for publication in the proceedings.

The health of Dr. Thomas S. Kirkbride, superintendent of the Pennsylvania Hospital Department for the Insane, has been poor for several months. It was at first considered to be only a malarial attack,

but it is now feared that it is some organic disease or growth involving the mesentery. But slight hopes are entertained that he will ever be able to resume his active duties. W.

PHILADELPHIA, January 6, 1880.

JABORANDI.

MR. EDITOR.—Dr. F. H. Cilley, Barnet, Vt., reports that Mrs. H., aged fifty-five, who had had dropsy during the last five years, with valvular disease of the heart, on June 18th had severe dyspnoea; she had passed no urine for twenty-four hours, and had general anasarca. Half-drachm doses of the fluid extract of jaborandi were given every four hours. Its effect was manifested in half an hour; within eighteen hours she passed sixteen pints of urine; also profuse perspiration and salivation were induced. The dyspnoea was at once relieved. A second attack was relieved by the same treatment. The patient has had tonics during the last four months, and is now in good condition.

WM. CHILD.

BATH, N. H., December 22, 1879.

REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 3, 1880.

Two thousand four hundred and six deaths were reported; 779 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 483, consumption 368,

lung diseases 310, diphtheria and croup 224, scarlet fever 77, typhoid fever 66, diarrhoeal diseases 27, measles 24, whooping-cough 21, erysipelas 17, malarial fevers 11, cerebro-spinal meningitis 10, small-pox six. From measles, New York 12, Chi-

cago six, Brooklyn three, Philadelphia two, St. Louis one. From *whooping-cough*, New York nine, Boston five, New Orleans and Pittsburgh two, Baltimore, District of Columbia, and Taunton one. From *erysipelas*, New York three, Philadelphia and Boston two, Chicago, St. Louis, Cincinnati, New Orleans, Cleveland, Milwaukee, Charleston, Nashville, Lawrence, and Gloucester one. From *malarial fevers*, New York and Brooklyn three, New Orleans two, Chicago, Baltimore, and District of Columbia one. From *cerebro-spinal meningitis*, St. Louis three, New York and District of Columbia two, Philadelphia, Chicago, and Milwaukee one. From *small-pox*, Philadelphia and District of Columbia three. During the month of December, consumption, lung diseases, and diphtheria were the prominent causes of death in Norfolk; typhoid fever, small-pox, measles, and scarlet fever are not reported.

The total mortality was somewhat greater than for the previous week,—of young children less. Typhoid fever was very much more fatal, consumption, measles, and erysipelas considerably so, the total of principal "zymotics" being without change. Lung diseases, whooping-cough, diarrhoeal diseases, diphtheria, and scarlet fever remained about as in the previous week. Small-pox is apparently increasing in Philadelphia and District of Columbia; general vaccination has been advised by the State Board in Massachusetts, and the disease there seems to have been kept under control. The severe epidemic of scarlet fever in Providence has lasted since the middle of October; there was a smaller death-rate from it during the past week than in the previous month. In 28 cities and towns of Massachusetts, with an estimated population of 833,900, the death-rate was 20.65; scarlet fever is very prevalent only in Fall River; lung diseases and diphtheria are the chief sources of mortality, next to consumption.

For the week ending December 13th, in 28 larger cities and towns of Belgium, the death-rate was 34.2; in 24 smaller towns 28.3. In the 52 cities and towns, with an estimated population of 1,511,003, bronchitis and pneumonia caused 187 deaths, consumption 76, diarrhoeal diseases 55, small pox 23, whooping-cough 15, typhoid fever 13, measles 13, croup nine, scarlet fever four, diphtheria three. There were in all 894 deaths, 318 of children under five years of age. In Brussels the death-rate was 27.0; Antwerp 31.6; Ghent 28.4; Liège 32.4. Lung diseases, scarlet fever, and diphtheria were prevalent in Holland; lung diseases, diarrhoea, typhoid fever, small-pox, diphtheria and croup, and measles (in order of fatality) in France, only a few deaths being reported from whooping-cough and scarlet fever; lung diseases, diphtheria, diarrhoea, scarlet fever, typhoid fever, whooping-cough, and to a less extent measles, in Germany; in Switzerland lung diseases, diarrhoea, and diphtheria; in Austria lung diseases, diarrhoea, diphtheria and croup, small-pox, scarlet fever, and measles.

For the week ending December 20th, in the 20 English cities with an estimated population of 7,383,999, the death-rate was 30.5 against 30.6 of the previous week. Four thousand three hundred and sixteen deaths were reported: diseases of the respiratory organs 799, scarlet fever 183, measles 181, whooping-cough 163, fever 45, diarrhoea 32, diphtheria 21, small-pox (London) two. The great increase in whooping-cough and in lung diseases occurred chiefly in London. Other acute diseases remain essentially the same. The death-rates ranged from 16.8 in Brighton to 39.6 in Liverpool; London 31.8; Bristol 39.0; Birmingham 25.9; Manchester 35.9; Leeds 24.6. In Edinburgh 22, Glasgow 31, Dublin 49.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

NEUROTOMY OF THE OPTIC AND CILIARY NERVES AS A SUBSTITUTE FOR ENUCLEATION OF THE EYEBALL.¹

BY HENRY W. WILLIAMS, A. M., M. D.,
Professor of Ophthalmology in Harvard University.

For many years past, the great frequency with which eyes wholly or partially destroyed by injury, or disorganized by some forms of internal disease, may become the cause of sympathetic inflammation of the opposite eye has been generally recognized. So great has this danger been regarded that some of the highest authorities have advised the immediate removal of an eye considered to be hopelessly injured, without waiting for the manifestation of any threatening symptoms, in the dread that if these once appear it may be too late to prevent their extending to the previously sound eye.

Where this sacrifice has not been at once made, such eyes have been anxiously watched for months or years by the practitioner himself and by the patient, whom he had felt it his duty to warn of possible danger, in constant fear lest their existing state of quiet should be replaced by insidious morbid changes, which, though apparently trifling, might with little warning affect the other eye, and establish there a destructive inflammation.

These pathological influences are presumed to be transmitted by the ciliary nerves from the ciliary body in one eye to the same part in its fellow, and it is here that the morbid processes begin. It is evident that injuries involving the ciliary region, or conditions where it suffers from traction of scars in contiguous parts or is irritated by displacement or hardening of internal structures, are the principal, though not absolutely the sole, sources of danger.

How this action is exerted in producing sympathetic ophthalmia is yet undetermined.

These being the facts, and in view of such a terrible consequence as the complete loss of vision, together with the probability that the slight warning symptoms might pass unobserved, surgeons were justified in urging and performing enucleation of the nearly or quite useless eye.

But the responsibility assumed was a heavy one; in many cases eyes recovered after grave lesions, and for years, perhaps for a life-time, exhibited no signs giving the slightest occasion for alarm; the patient retaining an eyeball, without vision indeed, but still useful as a support for the lids, if not always ornamental. On the other hand, cases of seemingly trivial injury went on badly from the first, and gradually fell into a condition of subacute inflammation of the ciliary region, which presently became also developed in the other eye; or, when they had apparently recovered, and had continued for a longer or shorter time free from disquieting symptoms, they after a while became again irritable. Such secondary attacks might at any moment induce dangerous conditions in the other eye, or might perhaps subside, to be followed, at uncertain intervals and from slight causes, by other similar threatening outbreaks.

The proper course to follow often depended on the intelligence and the situation in life of the patient. If

he or his friends could not be relied on to observe the eye carefully, and give immediate attention to the first suspicious manifestation, or if the person's residence or circumstances would not permit him to obtain, in case of need, prompt and skillful advice, it might be evidently for his advantage to have the eye removed at once. If, on the other hand, he was a person of sense and good judgment, and especially if he could be kept under observation, or could at once procure suitable professional aid if needed, the operation could often be postponed or omitted.

Though the sacrifice of even a sightless eye was a costly one, it was nothing in comparison with the far greater loss which was thus averted, and, where the conditions seemed dubious, it was often thought better to accept this definite sacrifice rather than to take the risks of the possible alternative.

It may be that in the eagerness to avoid a greater evil than the removal of a diseased eyeball, the considerable chances that it might safely be retained, and its value in such case to its possessor, have sometimes been overlooked. It is very important to a poor man, who can ill afford an artificial eye, to be able to keep in the orbit even a shrunken and disfigured globe, for the sake of the support thus given to the lids, and the better conducting away of the secretions. If the person is in good circumstances, such a stump affords an infinitely better support to an artificial eye than the tissues in the orbit from which the globe has been entirely removed. If the diseased eye retains a moderately good appearance, it is usually more desirable and comfortable than even the best fitted artificial substitute.

To secure to the patient immunity from future risk without the inconveniences following enucleation, as well as to remove conspicuous deformity, or to enable the patient to wear an artificial eye with more comfort, excision of the anterior part of the injured or diseased globe may often be safely resorted to instead of its entire removal.

Another operative procedure, to which it is the purpose of this paper to call attention, apparently combining all the security afforded by enucleation with many great conservative advantages, has recently been brought to the notice of the profession by Dr. Schoeler, of Berlin. This consists in section of the principal nerves supplying the diseased eye, thus cutting off the medium through which sympathetic inflammation is excited in the healthy organ.

The several branches of ciliary nerves which proceed from the ophthalmic ganglion to enter the eyeball at its posterior part are clustered around and in close proximity to the optic nerve, and may be severed with the latter, the globe being left intact.

The operation is begun, after anesthesia, by raising with forceps a fold of conjunctiva and sub-conjunctival tissue over the insertion of the rectus internus, and dividing it with scissors. The muscle is then drawn forward with a strabismus hook and its tendon cut close to the scleral insertion. The scleral end of the tendon or a fold of conjunctiva may then be seized with the forceps and the globe turned outwards, and a strong pair of curved scissors being passed through the external wound and behind the globe, the blades are to be opened sufficiently to include the opticus and its surrounding ciliary nerves, which may then be severed at a single cut. The posterior ciliary arteries and the central artery of the retina being simultaneously divided, there is a con-

¹ Read before the Boston Society for Medical Improvement, January 13th.

siderable hæmorrhage, which largely diffuses itself through the orbital cellular tissue, into which the cut vessels retract; and this effusion cannot be prevented by pressure upon the eyeball, nor can the blood be evacuated to any great extent by keeping open a channel towards the external wound. The result of this diffusion is an immediate protrusion of the eyeball, and, usually, subsequent ecchymosis of the eyelids. Both of these conditions, however, subside under the use of cold compresses, sometimes within two or three days; in other cases, several days are required, but no other treatment is necessary.

The tendon of the rectus may be left to acquire a new connection with the sclera, or may be at once reunited with it by a fine suture, if this is thought desirable. The operation may be done by incision at the temporal side of the globe with division of the rectus externus, or by introducing the scissors between two of the recti muscles.

This neurotomy is nearly always followed by immediate relief from the ciliary or circumorbital pain which had been previously complained of; and the tenderness on pressure, as well as any other signs of sympathetic irritation, also quickly disappears. The injection subsides slowly, as would be expected. Pain, resulting from the orbital infiltration, is more or less felt, but is rarely considerable.

Expectations of excellent results from this neurotomy appear to be, theoretically, reasonably well founded; and experience confirms them. The prompt subsidence of the peculiar threatening symptoms of sympathetic affection augurs well for the future, and gives proof of the efficiency of the operation. The tortuous course of the ciliary nerves in the loose orbital tissue makes any subsequent reunion of their divided ends very improbable. The objection that atrophy of the globe may ensue, from deficient nutrition, seems unlikely to be realized, as the anterior ciliary vessels and nerve are probably sufficient for purposes of vitality; and if division of the posterior tendons of the muscle ever occurs they are probably reunited.

Neurotomy is probably of too recent application to warrant us in asserting positively that it will be invariably a preventive of sympathetic ophthalmia. Thus far, it has generally seemed to be effectual. Should any symptoms afterwards manifest themselves, the operation might be repeated, to cut any nerve filaments which possibly had escaped division at the time of the previous section. In case of failure as regards permanent relief, enucleation will still remain as an ultimate resort.

Cases may possibly occur where, after this operation has been done on greatly diseased eyes, cretaceous or bony transformations of the lens or choroid may take place, which, acting as foreign substance, may excite local inflammation. Here, though, if our expectations of neurotomy are justified, there would be no danger of sympathetic affection of the sound eye, it might be necessary to remove the foreign body through, or together with, the anterior part of the globe; leaving the sclera to form, with the muscles, a basis for an artificial eye.

If we admit for a moment, as a supposition, the possibility that neurotomy may sometimes fail to give the expected relief, and even further, that an eye might, exceptionally, be lost because an unsuccessful trial had been made of neurotomy to the delay of enucleation, the adoption of the less formidable operation would still

be the means of saving many eyes which are now sacrificed to the terror felt by the patient at the idea of parting with an eyeball which seems to him little diseased, or to the reluctance of himself and friends to believe that the danger is so great as has been represented, and their consequent delay in attending to warning symptoms; or even to the hesitation of the surgeon to recommend enucleation in some cases where he believes it should be done, but hopes it may somehow be avoided.

ON STRANGULATED VEINS OF THE UTERUS AND THE IMPORTANCE OF RESTORING THEIR CIRCULATION AND FUNCTION OF DRAINAGE, THEREBY PREVENTING ENGORGEMENT AND MORBID NUTRITION.¹

BY T. H. BECKLER, M. D., BALTIMORE, MD.

ANATOMY OF THE UTERUS.

DURING these days Sir James Y. Simpson published his operation of division of the cervix from within, as a means of relieving stricture of the uterine canal, and thereby preventing sterility. Having already for these objects practiced dilatation, I was then at a loss to see, and have since been unable to perceive, the necessity of substituting for simple and effective dilatation the hazardous and dangerous operation of dividing the neck, whether from within or from without, laterally, bilaterally, or otherwise. Dissecting the uterine arteries years ago, I noticed that, while the branches are sent to the uterus with tolerable uniformity, their distribution after entering the walls is most irregular, with one exception, which is that the primary branches with great regularity circle around or about the cervix where it joins the body of the uterus, and just where they would be divided in this operation of Sir James and his imitators. As the uterus in health has a very obscure sensibility, they seem to forget that it is richly endowed with organic and vaso-motor nerves of the easily impressible and extremely susceptible sympathetic system, a due regard to which would also prevent the too prodigal use of potassa fusa, Churchill's mixture, and other irritating, and at times highly exasperating, applications. In gynecology, as in the practice of all the other departments of medicine and surgery, the golden rule should be never to do anything which might, by the remotest possibility, do the patient harm.

The late Sir James and his surgical executors or imitators, without regard to the veins, arteries, lymphatics, muscular structure, and nervous organization of the cervix uteri, cut through it as if they were dealing with clay, dough, or some other perfectly homogeneous and inanimate mass. Division of the neck, to be effective, must be carried up as high as its union with the body of the womb. An operation of this sort, considering the proximity of the uterine arteries, must always be attended with danger to the life of the patient, especially if there be not a hospital assistant on hand to arrest dangerous hæmorrhage, should it occur. Sham or make-believe operations of this sort, hardly carried deeper than the fissure in a frost-bitten lip, can never be dangerous or advantageous to any one, unless it be to fill the pockets of a mountebank. Division of the neck is an operation which will not stand the test of time, and when the anatomy and

¹ Concluded from page 57.

physiology of the uterus come to be better understood it will be altogether abandoned in the cases for which it was initiated.

I have seen one case where it was necessary to dilate the canal of the cervix at its junction with the body after the former had been deeply incised. I have seen also the case of a lady who, for five years bedridden with strumous infarction of the womb, voluminous in size, finally had the thickened walls of the cervix incised by the lateral operation, deeply through the entire length of its canal quite up to the body of the uterus, but with what object it was difficult to understand; at the end of five months the lips of the wound, which at their union must have been from an inch and a half broad, were gaping apart, had made no attempt at cicatrization, and it was only after the infarction was relieved, as it might have been at first and without the operation, by constitutional treatment, that the wound healed up and the patient recovered perfect health. The only prescription given her was the following:—

Ry Iodin.	gt. x.
Ferri iodidi	3ij.
Potassii iodidi	3ss.
Ext. cicute (coni) 1	3ij. M.

Et. pil. lxxx. S. One after each meal.

These pills should be made up quickly, adding half a drachm of gum acacia to keep the iodide of iron from deliquescing, and when made they should be coated with tolu.

Contraction of the constrictor cervicis muscle had nothing whatever to do with the above case, in either its origin or progress. There was simple closure of the cervical canal caused by pressure from without, produced by the thickened condition of the walls of the cervix from infarcted matter; and as soon as this infarction cleared up the womb resumed its healthy size, and the patient recovered her former health and activity.

This operation of the late Sir James Y. Simpson, and the modifications of it, is one that ought very rarely or never to be performed.

I recall the case of Mrs. A., the vaginal portion of whose womb was about two and a half inches long; and thinking that abbreviation, if not division, of it might possibly do good, I sent her, about fifteen years ago, to the New York Woman's Hospital; but after remaining there for a month, she returned to Baltimore without having been operated on, and I afterwards gave the surgeons in charge credit for their conservatism and masterly inactivity in this case. Had the opinions of to-day prevailed at that time, the neck would have

been taken off with the knife or a silver ligature, and in London or Edinburgh it would have been destroyed with potassa fusa, or the caustic containing thirty per cent. of lime.

In those days, too, when the so-called science of gynecology had not been conceived, certainly not born, and still less named after certain Greek words, the late Professor Hodge invented his pessary, now so largely employed in all civilized countries for the relief of retroverted and retroflexed uteri, and one of the greatest boons ever conferred on the suffering gentler sex. I was one of the first, on the recommendation of Dr. Hodge, to use his pessary, which kept the uterus in its place, and was therefore palliative; but in every instance the dilating biongies were also used to overcome the muscular contraction of the constrictor cervicis, thereby releasing the venous circulation, obstruction to which, and consequent increased weight from engorgement, had originated and kept up the uterine displacement.

DILATATION BY BOUGIES; LEUCORRHEA.

The bougie was always carried up to the *bis fond* of the uterine cavity, or, in other words, as far as it would go; and then, to prevent its displacement, the lower third of the bougie was placed against the right thigh and fastened to it by a few turns of a cotton-muslin roller. To fatigue the fibres of the constrictor cervicis muscle, the dilator was allowed to remain in the uterus from twelve to sixteen, and rarely thirty-six, forty-eight, or seventy-two, hours. For that most common of all uterine troubles, for which nitrate of silver is so generally applied, with only tentative results,—I refer, of course, to hypertrophic enlargement of more or less of the vaginal portion of the uterus, with thickening, tumidity, redness, and often superficial ulceration of the lips surrounding the os tincæ, together with engorgement and enlargement of the muciparous follicles, just within the neck, and pouring out, as they always do in this condition, profuse secretion, or exudation, popularly called "whites," or fluor albus,—for this condition I have never applied nitrate of silver, but have, times without number, carried a large bougie up to the fundus of the uterus, allowing it to remain in the cervical canal twelve, sixteen, or twenty-four hours, and generally with more satisfactory results than from any other single expedient, topical or general. Here again the relief could be attributed only to overcoming contraction in the fibres of the constrictor cervicis muscle, releasing the venous circulation, and thereby preventing retardation of blood and consequent engorgement. The original and continued cause having been removed by the bougie, I have gen-

erally relieved existing engorgement by giving one or two Blancard's pills of iodide of iron after each meal; and when syrup of the iodide of iron can be had without free iodine in it the following may be substituted for the pills:—

R Syr. ferri iodidi ʒiiss.
Aque fol. aurantii ʒiiss. M.
S. A teaspoonful after each meal, in water.

The muciparous follicles, existing just within the os tincæ, and occupying the walls of the cervical canal for about an inch, are the sole and only sources of fluor albus. These follicles are often found enlarged and tumid, without other engorgement or trouble of any sort, in the tissues surrounding them. How could the profuse flow from these bodies, amounting often to half a pint a day, occur unless from tying up of the cervical veins, the fluid being derived by exosmosis of serum from the blood? Signal relief is often derived from introducing a bougie and allowing it to remain a sufficient length of time in the cervical canal, thereby releasing the veins, and allowing their return circulation to pass through them unimpeded. The obstruction to venous flow being thus relieved, existing engorgement in the muciparous follicles may be resolved by giving the following:—

R Hypophosphit. sodæ,
Hypophosphit. calcis āā ʒiij.
Hypophosphoric acid q. s. ad sat.
Aque destillatæ ʒvi. M.
S. Give a teaspoonful after each meal.

Pure phosphate of lime in the magma form is much better to prescribe in doses of ten grains, thrice daily, provided we can be sure of having it furnished in proper assimilable form by the apothecary.

AMENORRHEA; DYSMENORRHEA; STERILITY.

I have repeatedly adopted this same expedient of introducing the bougie for the relief of amenorrhœa, dysmenorrhœa, and sterility, usually in the two latter affections, a day or two before the expected return of the catamenia. A young lady from Kausas, nineteen years old, suffering from amenorrhœa, having been at school here for over a year, had taken all the usual emmenagogue remedies resorted to in such cases, had never menstruated in the regular way, but had suffered vicariously from epistaxis, hæmatemesis, and, a short time before I saw her, from hæmaturia. She was brought in from the country by the matron of the school. I introduced a large bougie quite up to the fundus of the uterus, fastening the lower third of it, as usual, to the right thigh, with directions that on the following afternoon it should be removed. Ten days having elapsed, I received a note from the duenna, saying that her young lady was quite relieved.

In 1873, I was consulted by a lady as to what should be done for her daughter, a young girl seventeen years old, suffering from dysmenorrhœa; in fact, during three years she had never had anything beyond a mere show, which had appeared on some three or four occasions only, and always attended with severe hystericalgia. I introduced, in the way already described, a No. 10 urethral bougie, instructing the mother to remove it the next day. Three months after, I received a letter of thanks from the mother, stating that, as far as she could judge, her daughter was perfectly well, having had for two months perfectly regular visitations of the "enemy."

In the case of a lady four years married without conceiving, the same practice was resorted to, with

happy results, the only drawback being that four weeks after the first operation she insisted on its being repeated, and the result was that at the first period of gestation she was delivered of an acephalous monster, attributable, no doubt, to the second needless introduction of the dilator. She has since, however, proved a fruitful vine, having had in twelve years no less than eight children at the full period of gestation.

It happens often after parturition that the constrictor oris et cervicis uteri muscle contracts unduly, thereby narrowing the canal of the cervix and retarding the return of blood through the uterine veins. A lady with one child, a daughter sixteen years old, anxious to gratify still further the instinct of maternity, consulted me to know how her reproductive organs might be renovated. Having full faith in the invariableness of the cause of this and numerous other troubles of the womb, I advised that a large-sized urethral bougie be introduced quite up to the fundus of the uterus, which was done,—the dilator in this instance being allowed to remain undisturbed for over two days before removal. Shortly afterwards the lady became pregnant, and has since had four children at full term.

VAGINISMUS.

There is another condition for the cure of which the knife ought never to be resorted to, and that is for vaginismus, which is in all cases perfectly susceptible of relief without the use of a scalpel. A lovely and perfectly healthy young woman, residing in this city, only a door from the one already referred to as having died at Edinburgh from hæmorrhage following division of the neck of the uterus, went to Paris, where she was operated on, a knife being used to divide the sphincter vaginæ muscle, and the result was death from pyæmia shortly after the operation.

Why all this cutting and slashing in cases which can be relieved by simple methods, unattended with danger of any sort? Were these women properly advised, before being operated on, of the danger they were going to encounter? With provident knowledge of the risks, they might have preferred to select a child from the thousands in foundling hospitals, rather than knowingly incur the hazard to their lives of trying to become fruitful by operations, doubtful at best as to their efficacy. If we are cognizant of these two unnecessarily fatal cases coming from a single block on the same street, in a remote town, what must be the unknown and untold necrological list of dumb thousands from other more extended and populous regions? Why do not gynecologists confine their operations to the special province which they have voluntarily chosen? Dr. Francia governed Paraguay autocratically all his life without going beyond its borders. Several gynecologists have lately cut through the walls of the abdomen and into the gall-bladder for the purpose of removing therefrom cholesteric calculi, which might readily have been dissolved, and operations so hopelessly perilous avoided. Where a woman has closed her reproductive account, and declared an act of non-intercourse, Dr. J. Marion Sims's operation of reviving the surfaces of the vagina and taking a reef in them makes a very fair cup-and-ball arrangement for the relief of proclitidia; but it is only applicable in a limited number of cases, and whether this operation be performed or not, the cervical canal ought in all cases to be dilated to the size of its former healthy gauge, the veins released, and drainage restored,

whereby any chronic engorgement and increased weight which gave origin and continuance to the procidentia may be relieved.

AMPUTATION OF THE CERVIX.

As to excision or amputation of the cervix, I have never known a single instance where advantage to the patient resulted therefrom. One of the instruments used for this operation resembles a miniature or toy guillotine, worked by hand instead of by machinery. In long-standing cases of obstinate procidentia, where the uterus and its appendages were, and had been for a long time, hanging down to the middle third of the thighs, I have seen the entire mass removed, with signal relief to the patient.

In transient contraction of the constrictor cervicis uteri muscle, occurring usually at the catamenial period, attended with hypogastric pains, and sometimes by a mere show, often resembling coffee-grounds, the flow has been brought on by directing the attendant to apply on the end of her forefinger, carried deep down into the vagina, a wad of raw cotton, soaked in a solution of belladonna. In what manner could this agent, thus applied, afford relief, except by relaxing the fibres of the constrictor cervicis uteri muscle, which may have been put in a state of tension by irritating matters in the cervical canal? It is, no doubt, by washing out offending secretions and removing the cause of muscular contraction that warm-water injections often, under like circumstances, are useful.

If all physicians engaged in general medical and surgical practice will only treat in their incipency, by the simple method herein detailed, all the morbid conditions to which this paper refers, they will, without risk of any sort to their patients, ward off and relieve an incredible amount of human suffering. They need not fear that there will not still be, from neglect and inattention of their patients, a plenty of cases developing, maturing, and ripening for the knife, manipulations, and tractations of the gynecologist. A patient rarely applies to the gynecologist until her malady, whatever it may chance to be, is fully developed; it is generally perfect, and a specimen of its kind. Prevention and early recovery can therefore lay their claims on the general practitioner only, who is called to see these cases in their very incipency.

Dilatation of the cervical canal will, in fact, be found a simple and effective treatment for all young females who, for weeks together, realize that they have backs. "My back hurts me so when I walk or stand up, and often when I sit still; and then the pain in my limbs! The least fatigue gives me headache, and obliges me to lie down." In the early days of such complainings there is, in ninety-nine out of every hundred cases, contraction of the constrictor cervicis muscle, which, if not relieved, will result in engorgement of the neck, in tumidity of the muciparous follicles, giving rise to whites, leucorrhoea, or some one of the many ills already referred to. The bougie can, with the aid of a speculum, be easily introduced; but without such aid, knack or tact, readily acquired by practice, is needed. If the bougie be used in time, the maladies herein enumerated will be prevented, and where they have already occurred dilatation in all of them is still the most direct route to recovery.

ADVANCES IN UTERINE SURGERY.

The great contributions to the surgery of the uterus and its appendages are McDowell's radical method of

treating ovarian tumors by excision, Hodge's pessary, Dr. J. Marion Sims's operation for recto-vesico-vaginal fistula, Dr. Atlee's paper on encysted fibroid tumors, and Dr. G. Thomas's ingenious provision for early descent of the umbilical cord, wherein he converts the anterior walls of the vagina and uterus into an inclined plane by placing the patient on her elbows and knees.

MCDOWELL AND OVARIOTOMY.

When the circumstances under which McDowell devised and performed his first operation for ovariectomy are considered, it makes it altogether the most remarkable contribution ever made to general surgery, living as he did at that time in a remote Western village, only accessible by bridle paths or very imperfect roads, and where opportunities for the study of morbid anatomy must, to say the least, have been very few. He not only recognized the true nature of the morbid growth, but instituted the radical operation for its relief. The only explanation of this marvel is that he had time for reflection, opportunities for free thought, and was removed from the dogmatic teachings of the schools.

Almost as much may be said of the operation for vesico and recto vaginal fistula, originated by Dr. Sims, who is also the inventor of most of the instruments, of which there are quite too many, now used by the gynecologists. Dr. Thomas's provision against primary descent of the cord belongs to the same order of discovery. All of these remarkable operations were bestowals on an extended and comprehensive science. But after this province revolted and made a predatory raid on the empire of general surgery, it gained no victories, and since its organization into a special corps, with its exclusive society and separate and distinct journals or organs, few laurels have been won, no triumphs proclaimed, and little except detail has been added to the knowledge of uterine affections.

The secession carried with it all the brilliant discoveries which had previously been made in this department of surgery, and in fact there would have been nothing to gain by a raid had there not been much to carry off. The gynecologists would have been able to make just as good a showing had they continued under the banners of general medicine and surgery.

It is curious, but nevertheless true, that, abroad at least, those who repeat these operations, whether for ovariectomy, vesico-vaginal fistula, extraction of fibroids, or returning the cord on nature's inclined plane, seem to think that they all deserve equal credit, and are entitled to stand on the same platform with McDowell, Hodge, Sims, Atlee, and Thomas.

As well might a telegraph operator regard himself as equal to Morse, an exhibitor of chloroform the peer of Morton, the taker of a photograph the image of Daguerre, or he who adopts the new application of the law of gravitation consider himself the equal of Dr. Thomas. Perhaps they think that as none of these operations are European in their origin, but all imported from America, each surgeon has a right to win and wear parasitically the honors deducible from them.

It is the simplicity of these operations which constitutes their great merit. Ovariectomy in its performance according to the rules established requires only moderate skill and attention to details. There are no important blood-vessels or nerves to be avoided, and therefore acquaintance with anatomy is not called into

play. As a proof that no great surgical proficiency, knowledge, skill, or experience is required in ovariectomy, it is only necessary to remark that Dr. Keith, of Edinburgh, who as a specialty took up this operation, having never performed any other, was not educated as a surgeon, nor had he any experience in that department, and yet his tables show better success than those of any other ovariectomist. I had this statement from the lips of Keith himself.

There lived in a district near Baltimore a famous character, rejoicing in the name of Jack Beach, widely known amongst country people as the right man to spay and castrate pigs, caponize chickens, make geldings, and emasculate other animals. His instruments consisted of a clasp knife with a blade about four inches long, a rough curved needle, and horse-hair for sutures and for making draw-loops for caponizing fowls. I have seen him spay a dozen female pigs and castrate as many boars within the space of two hours. When asked why he operated, the reply was, "Cause, ye knows, it makes de animals take on fat." Of all the operations on living creatures, caponizing fowls is one of the most delicate, requiring a rare combination of knack, dexterity, and adroitness of touch, possessed by only a few individuals. Jack was known as and believed himself to be, as he certainly was in his way, a great "cracker." His operations, amounting in his latter days to thousands, were generally successful, and with the exception of losing a few caponized cocks, a fatal case in other creatures was never mentioned. If Jack's biography had been written and his fame known, the renown of Frère Jacques, the lithotomist, would have paled before it.

THE PRESENT STATE OF GYNÆCOLOGY.

The truth is, gynæcology lacks the dignity of the older specialties, — those of the eye and ear, for example. It came into being less than a score of years ago, and, like the juvenile and rollicking student just fledged, with a diploma and invested with the title of M. D. after a probation of eight months at an alma mater never known to produce anything but premature fruit, its disciples feel replete with all knowledge, believe that their particular art is perfect, and has only to be kept free from heretical accretions of every sort, whether from within their own charmed circle, or without from the profession at large. They engage in angry disputations and personal conflicts. Instead of wasting their time and talent in this manner, would it not be better for them to apply both in investigating the anatomy and physiology of the uterus and its appendages, the knowledge of both being very defective? — besides which they have before them the entire field of embryology. We all believed for a long time that the anatomy of the eye was tolerably well understood, and yet when I was in Berlin, in 1867, Von Graefe and Virchow were engaged in examining microscopically the cornea, and the latter showed me a drawing which had just been finished by one of his students, exhibiting minute nerves passing through this structure in lines corresponding with the diameter of its arc. Investigations of this sort applied to the uterus and its appendages, about which comparatively little is known, might prove of great value to the profession at large.

A famous gynæcologist boasted to a friend of mine that he had not in ten years read a single line in any medical book or journal. Fortunate man, to have his aspirations tally with the limited professional sphere

in which he lives, moves, and has his being, and the perfunctory operations he is called on daily to perform! With rich and promising fields before them, the gynæcologists have added not a jot to our previous knowledge of the anatomy and physiology of an organ which, though deficient in sensibility and voluntary motion, is nevertheless endowed with organic instincts of the highest order; and yet, in the absence of such knowledge, they go on to cut, hack, slash, and probe the uterus, besides using too frequently sponge and sea-tangle tents to dilate its neck, and throw into its cavity Churchill's mixture and other fluids of a highly irritating and exasperating character. They claim to be considered the directors, administrators, and trustees of important branches of medicine and surgery, and show that some master hand is needed to lay before them and others the work to be accomplished. If an individual limits his horizon to the os externum, his explorations to the os internum, and employs his time in the unvaried monotony of operations related therewith, there is danger, if he be a man of broad views, that he will in time become himself either hysterical, or a hysteromaniac.

From non-observance of the precepts herein contained the practices or *cliches* of all general practitioners have been and must continue to be hot-beds and nurseries wherein blooming cervixes, fibroids, ovarian cysts, and numerous other flowers and fruits are germinated, reared, and preserved exclusively for the conservatories and surgical tables of the gynæcologists.

The views expressed in this paper were taught and practiced in the women's ward of the Baltimore City and County Almshouse during 1848 and previous years, and it is hoped that the writer will be pardoned for bringing forward at this late date an epitome of ideas which advanced gynæcologists will no doubt regard as so very primitive and extremely elementary. The work of gynæcologists for the past twenty years has been almost exclusively surgical. Had they done as much in elucidating the anatomy of the fibrous structures, arteries, veins, lymphatics, nerves, erectile tissues, endometrium, and ovaria, besides showing the relations of these different structures to and dependence on each other, both in a state of rest and in the conditions of evolution, and had given more attention to embryology, the whole subject would at this time have been better understood. We have hope at least that biologists will in the next twenty years anatomize the different layers and important muscular bands of the uterus and its appendages, and not only measure their force, but point out the direction in which, and to what end, the power is applied.

Nor has anything been done in the past thirty years to teach the value of internal remedies in affections of the womb. Plenty of steel is used, but in a very compact form and having a very keen edge. Dr. Tilt has published a volume on Uterine Therapeutics, but it is disappointing to find that, beyond giving a list of remedies and speaking in general terms only of their therapeutic qualities, little is said except about surgery and topical applications. There are many good gynæcological surgeons, but no therapist capable of diagnosing and treating uterine affections without a resort to the knife has yet appeared. A surgeon in Paris probed the wound of a man who had shot himself through the brain with a large pistol ball. The charge for the operation was, say, six thousand francs. The executors protesting, he said, "Had I written a prescrip-

tion for the late Mr. C., my charge would have been ten francs; but when we take up an instrument and use it, the patient or his estate is expected to pay liberally."

SUMMARY.

I endeavored to show at the beginning that the active state of the constrictor cervicis muscle is in the period of gestation, during which process it is transformed into the constrictor oris uteri, but that in the dormant condition of the unimpregnated uterus this muscle becomes very often like an idle individual, mischievous, converting by morbid compression the veins underlying it, not into mythical, but into actual closed Pandora boxes. From the very beginning to the end of pregnancy, the life of this muscle is evolution and growth, and its office that of a support, whereby it is prepared for a supreme effort during and after parturition; but in the dormant state of the unimpregnated uterus its slow, feeble, and stealthy, but persistent, contractions are, when they occur, always morbid. The relation this constrictor muscle bears to the veins of the cervix, and the agency or *vis morbi* it possesses of becoming by closing them a *causa morborum*, thereby producing multiform diseases, have never, so far as is known, been even hinted at, much less described, by any medical, surgical, or physio-pathological writer.

The disease-producing power of this muscle and the antagonist to it, that is to say, the agency exerted by the bougie in preventing, dissipating, or annulling the decrees of this autocratic band of fibres, are both well expressed in the phrase *vis morbi distracta per artus*; here the muscle represents the *vis morbi*, while the *distracta per artus* is typified in the use of the bougie to arrest its morbid action. It may be doubted whether in the whole field of medicine and surgery an example can be found to illustrate more clearly the truth and significance of the above aphorism. Dilating the cervical canal to its *normal calibre, not beyond*, and allowing the bougie to remain in it *sufficiently long to fatigue the constrictor cervicis muscle*, are also the best means of relieving what Virchow and Dr. Gaillard Thomas have been pleased to call areolar hyperplasia, in lieu of the engorgement of Li-franc and the subinvolution, chronic metritis, or hyperæmia of other authors, who, under various synonyms, have made this condition such a terrible bone of contention as to its mode of production and true character. I have always regarded it as a hæmorrhage, or passive congestion, and in its advanced stages, as hypertrophy of all the tissues, caused by morbid nutrition resulting from obstruction to the venous circulation. In this condition *ergot* should be used as the adjuvant, and in chronic cases dilatation may have to be repeated at intervals of ten, twenty, or thirty days.

For this muscle, occupying a perfectly unique position, and capable by its morbid contractions of producing not only numerous diseases of the uterus and its appendages, but also disturbances of the entire female economy, a new name is wanted.

Dr. Mackintosh, of Edinburgh, reports twenty-four cases, out of twenty-seven, relieved by dilatation of the cervical canal with metallic rods, a practice unwisely abandoned, showing as it did most excellent results, especially when it is remembered that the metallic rods were not permitted to remain in the uterus for any length of time, and that they were used without knowledge of the mode in which relief by dilatation was to be obtained.

In Dr. T. Gaillard Thomas's admirable work on the diseases of women, it may be seen that in his chapters on areolar hyperplasia and dysmenorrhœa he speaks of the obscurity of uterine pathology and the want of some undiscovered key to the knowledge of it. It is hoped that this short paper may assist him and others in finding the missing key.

It has been seen that the object of this paper was and is to explain the ætiology of numerous uterine affections, but the inquirers after truth, who do not like the foregoing explanations, and believe that the key to these diseases has not been discovered, are free to search after some more satisfactory solution of their mode of production, remembering, however, that where one ascertained cause is sufficient to account for a series of sequences, it is unphilosophical to look for any other, and recollecting also that as the simple method of dilatation by freeing the veins removes, as it has been shown to do, the cause, its disease-producing effects must in like manner be prevented.

[NOTE. The author was in error in attributing to Sir Astley Cooper the plate referred to in the beginning of this article.

T. H. B.]

BALTIMORE, November 29, 1879.

RECENT PROGRESS IN THE TREATMENT OF CHILDREN'S DISEASES.¹

BY D. H. HAYDEN, M. D.

Clinical Studies of the Hemorrhages in Whooping-Cough, and of Hemoptysis and False Hemoptysis.—Professor Henri Roger,² at a meeting of the Academy of Medicine of Paris, held September 16, 1879, read a paper on the above subject. He first spoke of the epistaxis which is produced by the convulsive shaking of the cough, and which rarely becomes dangerous by its abundance or by the frequency of its repetition, unless associated with an alteration of the blood; of subconjunctival or palpebral ecchymoses, equally dependent upon the paroxysm, and seeming sometimes to differentiate the cough of pertussis from common bronchitis; of otorrhagia purpurica; and of certain visceral hemorrhages.

The study of hæmoptysis and hæmatemesis was then taken up, and M. Roger demonstrated by numerous observations that these hæmorrhages are altogether exceptional in infants, being in nearly all cases a false hæmoptysis, the blood coming from the nasal fossæ, pharynx, mouth, or gums, and never from the pulmonary organs.

After epistaxis the more frequent source of the blood is from the mouth. In this region the congestion is excessive at the time of the paroxysms; the gums become swollen, fungous, and bleeding; the tongue, violently thrust out of the mouth at this time, becomes eroded by the rubbing of its inferior surface against the lower teeth, as the frequent ulcerations of the frænum bear witness to; sometimes it is bitten. The lips are dry, and the little patient often tears off the epidermis. Every ulceration or erosion, however small, pours out blood during the paroxysm. The source of the bleeding in buccal hæmorrhages is sometimes the gums, sometimes a solution of continuity of the mucous membrane of the mouth or tongue; and

¹ Concluded from page 59.

² Gazette hebdomadaire, September 19, 1879.

the blood can come, too, from the pharynx or the nose, throwing into the shade that originating in the mouth.

It is only at the end of the paroxysm that the child ejects a bloody frothy sputa, caused by the intimate mixture of the blood with mucus from the bronchial tubes, which has been beaten up and aerated by the shaking of the cough. This has no serious significance, and yet there are few symptoms that occasion greater alarm to the relations, and even to the physician, the reason being that they confound this symptom with hæmoptysis. M. Roger has more than once rectified errors in this respect, and has been able to calm inquietude, all the more legitimate that children with prolonged cases of whooping-cough are often suspected to be tuberculous. An examination of the mouth would show the source of the bleeding; and in interpreting the facts it is necessary to remember that a pulmonary hæmorrhage of tuberculous origin is excessively rare in children. Even if the hæmoptysis were a real one, it would not be rational to conclude from this the existence of pulmonary tuberculosis. It is only after the tenth year that children are liable to hæmoptysis, and even then it is rare that this accident marks the commencement of phthisis, as is the case with adults. In early infancy it can be said that hæmoptysis never occurs as the initial symptom of phthisis.

In the same way that in whooping-cough there is a false hæmoptysis, there is also a false hæmatemesis. By examination of the nasal fossæ it will be always found that the blood comes from an epistaxis, having run down from the posterior nares, often insensibly, into the cavity of the stomach, where it can accumulate in large amount. If the blood should be expelled all at once by an intolerant stomach, the bleeding from the anterior or posterior nostril would be still visible; if evacuated slowly after the epistaxis had ceased, a few drops or clots in the nose could signalize the source of the hæmorrhage.

It is essential to recollect that hæmatemesis, like hæmoptysis, is altogether exceptional in early life, and is met with only in very rare cases of purpura hæmorrhagica. If in any disease whatever, — and this holds good especially in whooping-cough, — a mother in great alarm shows a vessel filled with blood ejected by the mouth, the physician, guided by the laws of infantile pathology, can reassure both her and himself; for it is almost a certainty that it is the result of an epistaxis, the blood having penetrated into the stomach, and subsequently been expelled by an attack of coughing.

Two kinds of hæmorrhage should therefore be erased from the list of complications of whooping-cough, namely, hæmatemesis and hæmoptysis, and by a more accurate diagnosis the errors of prognosis will become thereby corrected, and a more proper estimation be placed upon facts which might otherwise be thought alarming, but which will be seen to offer no forebodings of danger.

*Treatment of Pertussis by Inhalation.*¹ — During last April and May several cases of whooping-cough were received in the quarantine wards of the New York Foundling Asylum, and as treatment by the remedies which are in common use (belladonna, quinia, and the bromides) had not been as successful in former cases as was desired, Dr. Smith decided to try inhalations. The spray of the following mixture was in-

haled from the steam atomizer three times daily, and from two to five minutes at each sitting: —

Ry	Acidi carbolici	3ss.
	Potass. chlorat.	ij.
	Glycerinæ	ij.
	Aquæ	3vi. M.

The treatment was begun about the middle of April and continued through May. The number of patients submitted to this treatment was twelve. While this was too small a number to furnish any positive conclusions as to the utility of the spray, the effect was sufficiently favorable to justify further trial. The cases were milder than the average, occurring in the declining period of an epidemic. Seven of the cases, the youngest being eight months and the oldest five years, are reported, and all show a decided diminution in the daily number of paroxysms following the employment of the inhalation.

The chief danger in this disease is in the period of spasmodic cough, and is usually proportionate to the severity of the cough. If the cough is mild, complications, as convulsions, atelectasis, pneumonia, etc., are not apt to occur. Hence the physician very properly endeavors to ameliorate the cough, knowing that in proportion as it becomes mild the prognosis improves. The cough can no doubt be rendered milder and less frequent by a considerable number of medicines, chiefly such as diminish "reflex irritability" and procure sleep. Hence there is a long list of remedies which have been recommended by physicians of experience. In the *Index of Therapeutics*, appended to Stillé and Maisch's *National Dispensatory*, thirty drugs are named which are supposed to be useful in whooping-cough. Agents to diminish the frequency and severity of the cough, the bromides to prevent convulsions, quinia to reduce fever and support strength when the bronchial catarrh has extended so as to become a complication, or pneumonia has arisen, the timely use of opium and bismuth to check intestinal catarrh, and the more general use of stimulants have in recent years greatly reduced the mortality from pertussis. Therefore, cases now have a favorable issue which with the different treatment of former times would inevitably perish. From having been one of the most fatal maladies fifty years ago, so that in New York one died of whooping-cough in every seventy-six deaths from all causes, it is now less fatal than almost any other severe contagious malady.

It is obvious that if a spray can be inhaled with perfect safety which controls the paroxysms, thus enabling us to dispense with the use of active internal agents, except as special indications arise, an important gain will be achieved in the treatment of pertussis, and Dr. Smith feels encouraged, by the results of the above treatment, in the belief that inhalation will yet be more generally used to ameliorate the cough.

There appears to be an exaggerated sensitiveness of the laryngeal filaments of the pneumogastric in this malady, so that inspiration of air, as in crying or laughing, or a current of cold air passing over the laryngeal surface, or the lodgment of mucus upon it, immediately excites the cough, notwithstanding the efforts of the patient to repress it.

The good effect of the spray in the above cases seems to have been largely due to the carbolic acid, which, when used locally, is known to produce an anæsthetic effect on mucous surfaces; but in one or two instances in which the chlorate was temporarily omitted from the mixture patients seemed to do better with than without it.

¹ By J. Lewis Smith, M. D., Clinical Professor of Diseases of Children in the Bellevue Hospital Medical College, New York. The *American Journal of the Medical Sciences*, October, 1879.

However desirable it may be to ameliorate the cough, sustaining measures are required in most cases during the spasmodic stage and in convalescence. Dr. Smith speaks highly of beef, wine, and iron, as now prepared by pharmacists, for these patients, given in teaspoonful doses every two hours to a child two years old.

[Birch-Hirschfeld¹ reports to have had very satisfactory experiences with the use of carbolic-acid inhalations in the treatment of pertussis. In his cases the patients were confined in a room (otherwise well ventilated) the air of which was impregnated with carbolic-acid spray (twenty per cent. solution) by means of a steam atomizer. Dr. E. Thorne, of Berlin,² reports a very beneficial effect upon the number and violence of the paroxysms with the use of a one to two per cent. solution of carbolic acid in a steam-inhaling apparatus. The method of employment was quite similar to that recommended by Dr. Smith. — REP.]

*Sixteenth Annual Report of the Jenner Children's Hospital in Berne for 1878.*³ — Professor Demme, after giving a statistical summary of the hospital and out-patient practice for the year, speaks of the intestinal troubles of infants, and especially of the abundant development of vegetable parasites (entero-mycosis) found in the intestines of these patients. In two fatal cases of this description, with a high terminal fever, as in Buhl's case,⁴ the lacteal vessels and mesenteric glands were found filled with micrococci. In addition to a careful regulation of the diet (the mother's milk, if possible) and an avoidance of amylaceous or sugar-containing substances, Demme has found cognac, properly diluted and freely given, to be extremely useful in these cases, with or without creasote, opium, etc.; also benzoate of soda.

The latter remedy was used with good effect in cases of diphtheria (scarlatinal and idiopathic). Of twenty-seven severe cases of diphtheria thus treated six terminated fatally. It was given internally in daily doses of two and a half grammes (thirty-seven grains) to infants from three to six months old, and five grammes (seventy-five grains) in the twenty-four hours was the amount employed for those between six months and one year of age, gradually increasing this quantity with increasing age, so that children from eight to fifteen years took daily twelve to fifteen grammes (three to four drachms) without injurious effect. It was also applied locally by insufflation, or in a more or less strong solution as a gargle.

Among other diseases reported is a case of diabetes insipidus in a boy six years old, where a swelling of the right leg and light multiple swellings of the glands excited the suspicion of syphilis. Treatment with iodide of potash produced a partial, mercurial inunction a complete cure. In a case of congenital encephalocele in a boy six years old, the swelling was brought down to a level with the bones of the cranium without any disturbance by means of a gentle steady pressure, with gradual increase. When this was rapidly augmented there followed sometimes convulsions, paleness of the skin and mucous membrane, loss of consciousness, and retention of urine lasting several hours.

In pursuance of his experiments with anaesthetics, Demme states that a mixture of one part of chloroform with one hundred parts of chloroform effects a somewhat slow but very quiet narcosis.

Two cases of operation for incarcerated inguinal hernia in infants two months old are reported; also the successful treatment of scrofulous swelling of glands by subcutaneous dissection, and a few cases of struma in children.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

CASES IN THE SERVICE OF DRs. ARNOLD AND MASON.

[REPORTED BY DR. H. HUN.]

Cases of Pelvic Inflammation. — CASE I. E. H., aged twenty, entered the hospital May 23d. She had been married two years, but never had had children. Catamenia regular. She had been well until eight weeks before entrance, when she began to have pain in the lower part of abdomen, which grew steadily worse, so that she could not lie on either side. She had had a number of chills and moderate diarrhoea. There had been night sweats, and she had lost much flesh and strength. The patient was very pale, emaciated, and weak.

She presented an elastic, obscurely fluctuating swelling behind the uterus, which was punctured by Dr. Arnold with Bixby's trocar on June 2d, and a pint of highly offensive pus was evacuated. The cavity was washed out with carbolic-acid solution, and a silver canula tied in. An abdominal poultice and hot vaginal douche were ordered.

June 4th. The silver canula caused so much distress that it was removed, and a drainage tube inserted. The drainage tube slipped out every few days, but was replaced each time, and the cavity washed out daily. The discharge of pus at first amounted to one or two ounces daily, but gradually diminished until the middle of July, when it ceased, the drainage tube having been omitted a few days before.

July 17th. The patient sat up for the first time.

August 10th. The uterus was slightly movable, anteflexed, and there was a hard mass in the right cul-de-sac, perceptible by abdominal palpation. At this time the patient had more color, was sitting up several hours every day, and was steadily improving. She had been taking quinia, iron, and laxatives.

August 23d. Discharged for misconduct.

September 4th. Dr. Arnold was called to see the patient outside the hospital, and found marked aggravation of all her symptoms, with tumefaction the size of a large orange, but no fluctuation in the region of the right ovary. The inflammation ran its usual course.

October 4th. Slight sense of fluctuation felt to the right and anterior to os uteri; tumefaction still to extreme right. Sound passed to the right thirty degrees from the median line; uterus fixed; pulse, 112; temperature, 102.4° F.; slight chill. Aspirator used, and about ten ounces of excessively fetid pus evacuated. The swelling in the abdomen subsided for a few days, and then began to return in the left side.

October 19th. A distinctly fluctuating mass was felt to the left of and anterior to the uterus, and was punctured with a bistoury, and afterwards dilated forcibly so as to admit the finger. This was followed by a carbolicized injection through a single catheter every third or fourth day. She has steadily im-

proved, and on December 9th was sitting up and moving about her room.

CASE II. E. D., aged twenty, single, entered the hospital May 31st. The catamenia had been rather irregular. Three weeks before, she began to be "unwell," continued to flow a little for about ten days; the flow then ceased, but began again three days before entrance. There had been much pain in the back and lower part of the abdomen, shooting down both legs. There was constant leucorrhœa.

The patient presented a soft, very fluctuating tumor in the right side of the pelvis, which could be felt above the pubes, and projected into the vagina as a small, tense bag just behind the cervix. On June 2d the tumor was punctured by Dr. Arnold with a Bixby's trocar, and a considerable quantity of purulent or fœtulent matter was evacuated. The cavity was washed out, and a silver canula tied in.

June 4th. The canula caused so much distress that it was removed, and a drainage tube was inserted. An abdominal poultice was applied, and the patient was given a hot vaginal douche twice a day.

June 6th. The drainage tube slipped out, and was not replaced, the cavity being washed out daily with a double catheter until June 22d, when this was omitted. The fistula in the vagina continued to discharge a small amount of pus.

Early in August the patient began to sit up every day. At this time the uterus was low down in the vagina and fixed. Some discharge continued, and there was marked tenderness, with moderate tumefaction in the right cul-de-sac. A small, hard mass was felt in the left cul-de-sac. The patient had taken iron, quinia, and laxatives. Towards the end of the month cod-liver oil and extract of malt were given, and she made marked improvement.

At the end of September the vaginal discharge had almost entirely ceased, and by the first of November the patient had much better color, though still pale, was out of bed all day, and could walk about without pain. At this time the cul-de-sacs were free, though some tenderness remained.

On November 21st she was discharged, to go to St. Luke's Convalescent Home, where she was seen about the middle of December, when she was looking and feeling perfectly well.

CASE III. B. A., aged nineteen, single, entered the hospital June 5th. The catamenia had been regular. The patient had never been very strong, and for the previous two months had had a poor appetite. For a week there had been constant pain in the left inguinal region, increased by standing. There had been one or two chills. No leucorrhœa.

The uterus was pressed down and back. The sound passed the normal distance, without pain, towards the promontory of the sacrum. There was a considerable tumefaction in the left pelvic region in front and at the side of the uterus, about the size of a large orange, with a sense of indistinct fluctuation.

This tumor was punctured on June 8th by Dr. Arnold with Bixby's trocar, and about half a pint of clear, yellow serum was evacuated. The cavity was not washed out. No canula nor drainage tube was left in. An abdominal poultice and hot vaginal douches were ordered.

From June 12th to 25th the patient had a severe attack of tonsillitis.

On June 27th, the pelvic tumor having refilled with

fluid, it was punctured again with Bixby's trocar, evacuating a considerable quantity of fetid purulent matter. A silver canula was tied in, and the cavity was washed out daily with a solution of carbolic acid.

On June 30th the canula was removed on account of the distress which it caused, and a drainage tube was inserted, which was also removed in a few days.

Patient continued to have for some time abdominal pain and slight diarrhœa, the discharge from the cavity gradually diminishing in amount.

August 20th. She sat up for the first time.

September 1st. Having previously been given quinia and iron, she began to take cod-liver oil and extract of malt, which was followed by rapid improvement.

September 27th. She left the hospital. At that time she had gained much flesh, and was looking well. There was no tenderness in either cul-de-sac. Slight induration about old seat of puncture. Uterus fairly movable. Little discharge, without odor. The patient was seen about a month later, after she had been at work two weeks, and was looking and feeling quite well.

CASE IV. E. C., aged twenty-three, married, was admitted July 29th. She had had two children, the youngest being two years old. Since the last child was born she had been weak, and had had pain in the lower part of the abdomen and leucorrhœa. Defecation had always been a little painful. In March, 1878, she entered the Massachusetts General Hospital, where she was operated on for laceration of the cervix and perineum. For the past few months she had been troubled by night sweats, and for two weeks had been quite sick, with pain in the lower part of the abdomen and vomiting. During the past week had had a number of chills. The night before admission she went down to supper as usual. Later in the evening she began to vomit and to have chills, and then had much pain in the abdomen. She did not sleep at all, and in the morning was cold and very faint, but rallied somewhat.

She was brought to the hospital at seven p. m. in a condition of collapse, with great abdominal pain. Pulse 122, very weak; temperature 103° F. Whiskey and morphia were given, but she did not rally well.

The os was pushed forward against the pubes. A large, tender bag of fluid pressed down the posterior cul-de-sac, not tense, but yielding readily before the finger. The abdomen was distended and tympanitic. The patient was etherized, the sac in the vagina was aspirated, and twenty ounces of thin, serous fluid of great fetor were withdrawn. The pulse was then scarcely perceptible and the skin cold.

On the afternoon of the next day, her pulse being a little stronger, the condition otherwise unchanged, she was brought into the operating room to have a drainage tube inserted, but no tumor could be felt in the posterior cul-de-sac.

From July 29th to August 9th she suffered from an attack of acute general peritonitis, the pulse varying for the first three days from 100 to 120, and afterwards from 120 to 130; the respirations from 38 to 50; the temperature from 100° to 103° F. for the first six days, afterwards from 99° to 100° F. The patient had great abdominal pain, tenderness, and tympanites, profuse perspiration each morning, diarrhœa, retention of urine, almost constant vomiting; she could retain a little milk, but no stimulants. The thighs were flexed on the abdomen. An abdominal poultice was applied, and the patient was given morphia in sufficient quan-

tity to control the pain: At first she required nearly a grain a day, later about half a grain.

On the evening of August 5th she was able to retain brandy for the first time, and after August 6th took eight ounces of brandy daily.

Ever since the entrance the patient had had an offensive, thin, watery vaginal discharge, very small in amount. On August 8th this discharge became very abundant, and on August 9th a pint of thick, yellow pus escaped from the vagina; in the afternoon the discharge was again watery, abundant, and very offensive. At this time she was having warm carbolized vaginal douches three times a day, and frequently in the day carbolic acid was sprinkled about the room to control the odor.

From this time the patient steadily improved. The offensive vaginal discharge continued. For several days it would be very scanty, and then a large quantity of thick pus would be discharged, but on the whole it steadily decreased in amount. The patient's temperature was usually normal in the morning, and every evening rose to 102° or 103° F., occasionally to 104° F. An exceptionally high evening temperature was usually followed by a free escape of pus. The pulse continued from 110 to 120; the respirations from 20 to 30.

September 5th. The cervix was in the normal position. There was some induration and tenderness in the posterior cul-de-sac.

September 15th. The patient sat up a little while to-day for the first time.

October 8th. Lately she has had almost no discharge from the vagina. Sits up most of the day, and walks about a little. Temperature still rises to 101° or 102° F. in the evening. Feels quite well, and insists on going home.

[REMARKS.—The four cases reported above, which remained in hospital for an average period of fifteen weeks, illustrate the usual tedious and exhausting course of pelvic inflammations, which are neglected at the outset often because they are unrecognized. The emaciation, debility, and anorexia in all were extreme; nutrition was with difficulty maintained. Case IV., however, which was the most unpromising, being complicated with general peritonitis, and in which constant drainage with washing out was not resorted to, made the quickest recovery.

In this case it was thought that a latent serous effusion of very fetid character ruptured into the peritoneum. It will be observed that the evacuated fluid in two instances was serous, subsequently becoming purulent.]

Shoulder Presentation, with Spontaneous Evolution in the Seventh Month.—H. L., aged twenty, married, was admitted September 7th. The catamenia had been regular. She had one child, three years ago, after an easy labor. The patient thought that she was last unwell in February. She felt the motion of a child two months before entrance. The day before admission she did considerable lifting, but felt no discomfort from it. About five o'clock in the afternoon, September 7th, she began to have slight gripping pains in the abdomen. Shortly before seven o'clock the pains became regular and severe. Half an hour later she noticed that she was flowing, and entered the hospital at eight p. m.

On entrance, the fundus was one inch above the umbilicus. The fetal head was felt in the left iliac fossa,

the breech slightly above the right iliac fossa. The fetal heart was heard (148) below and to the left of the umbilicus. Os high up, the size of a silver dollar. A peculiar, boggy-feeling mass on the right side of os. No fetal part was felt.

At 8.50 p. m., as the head could not be brought into the axis of the pelvic strait by abdominal manipulation, and there was considerable hemorrhage, the membranes were ruptured. The hemorrhage stopped almost completely. The head could now be felt far up on the patient's left, but could not be brought into the axis of the pelvic strait.

At 10.15 p. m., the pains were feeble and infrequent; the os was about half dilated, and slight hemorrhage had begun. A basinful of water as hot as the hand could bear was injected into the vagina. The pains then became of more force and more regular. Flowing ceased almost entirely; a little later a strong pain came on, and the left hand descended into the vagina, and protruded from the vulva. The appearance of the hand at the vulva was soon followed by the expulsion of a considerable amount of clotted blood. The left side of the thorax next presented at the vulva, then the buttocks, and the right hand came down spontaneously, and the fetus was expelled. There was no pulsation in the cord. There was very little hemorrhage. The fetus was fourteen inches in length; weight twenty-seven and a half ounces. The placenta presented at one portion of its circumference a dark red discoloration (apoplectic).

The convalescence was perfectly natural. The temperature did not rise above normal, except on September 13th, when it was 99° in the morning and 99.8° at night.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

JANUARY 13, 1880. DR. JAMES C. WHITE, permanent chairman, presided.

NEUROTOMY OF THE OPTIC AND CILIARY NERVES.

DR. H. W. WILLIAMS read a paper on Neurotomy of the Optic and Ciliary Nerves as a Substitute for Enucleation of the Eyeball, which is printed in full on page 73.

DR. H. DERBY spoke as follows: If the character given the operation of neurotomy by its friends is ultimately confirmed by experience, its adoption will mark a decided advance in ophthalmic surgery. Its advantages may be briefly recapitulated. If the eye left in place is a small one, an artificial eye receives better support and greater motion than could be the case after enucleation. If a large one, the expense and annoyance of an artificial eye are avoided. In the case of children enucleation impairs the development of the adjacent parts, while neurotomy would not interfere with it. Last, but not least, is the fact so justly dwelt on by Dr. Williams, that many a patient of limited intelligence or strong prejudices might consent to have the nerve cut, while steadfastly refusing to have the eye cut, and thus be saved from blindness.

While possessing these advantages, neurotomy is open to certain strong objections. First among these I reckon the attendant hemorrhage. This is in some

cases slight, in others considerable; is sometimes rapidly absorbed, at others disappears slowly. On theoretical grounds, why may not a clot of some size, pressing against the cut extremities of the optic and ciliary nerves, act as a source of irritation, and transmit an evil influence along these channels of communication with the other eye? It may also act in another way, and excite a proliferation of connective tissue that shall remain after its own disappearance. Pflüger¹ reports a case of neurotomy, attended by moderate hemorrhage, where the patient returned in a month and begged him to remove the eye, there being a feeling "as of a wall" behind it. He enucleated, and found, growing to the back of the eye, a mass of connective tissue, sixteen millimetres long and four millimetres thick. After this operation all symptoms of discomfort at once disappeared.

The other objection to neurotomy is a serious one: it is the danger that some of the severed nerves may reunite. The practical nature of this consideration may be illustrated by two cases. Schoeler² himself did a neurotomy for the prevention of sympathetic ophthalmia. Nine months later redness of the operated eye came on, and the patient presented himself. An application of atropine was made. As is well known, after neurotomy the pupil becomes motionless, failing to respond to light or darkness, to atropine or eserine. But in this case the pupil *dilated under atropine*, and some nerve reunion may hence be inferred. Unfortunately, the subsequent history of the case is wanting, as the patient disappeared.

A more striking instance is reported by Mauthner.³ An eye had been lost by a blow from a stick of wood. Vision had disappeared, tension diminished; the pupil was closed, and there was ciliary tenderness on pressure. The sound eye had lately exhibited intolerance of light, was occasionally the seat of pain, and could not be used continuously at his work. Neurotomy was at once performed. It was followed, as was to be expected, by anaesthesia of the cornea and disappearance of ciliary tenderness. The cornea subsequently regained sensitiveness, and the ciliary tenderness returned. Professor von Jaeger now enucleated, and the parts were found in the following condition: "The end of the optic nerve, attached to the bulb, consisted of two parts. The optic nerve had been indeed thoroughly divided at the neurotomy, but the two nerve ends had grown together again, the apposition of their surfaces being somewhat inaccurate, and the line of the cut distinctly visible." With the remote possibility, then, of the bleeding causing irritation, and a yet nearer possibility of nerve reunion, it seems to me that the operation of neurotomy cannot yet be unqualifiedly recommended as a substitute for enucleation.

DR. WADSWORTH said that the advantages of neurotomy were certainly very great, as had been well set forth by Dr. Williams. In the present state of experience on the question, however, he felt we could not decide positively just how much freedom from danger of subsequent sympathetic ophthalmia it conferred. Besides the cases referred to by Dr. Derby, in which pain had occurred after the operation, Schmidt-Rimpler had reported one where enucleation was required a year afterward on account of pain starting from the

eye. Dr. Wadsworth had operated only in six cases, but in one of these was obliged to enucleate later. The man was a patient in the Massachusetts General Hospital. He suffered from general rheumatism, and also had in the left eye total posterior synechia, cataract, loss of sight, and severe pain which lasted for a long time and was not relieved by the usual remedies. Neurotomy stopped the pain immediately, and the man went to work on a farm. But two months after the operation attacks of pain began again in the eye. He was seen still a month later, and had then had four or five attacks of pain, generally coming on during sleep, and lasting a few hours or through the next day. The globe was moderately congested, and there was some tenderness over the upper and outer ciliary region. The eye was enucleated. Over a space of about half an inch in diameter, the posterior surface of the eye was firmly attached to the parts behind it. Dr. Wadsworth was inclined to believe that the pain here was not due to reunion of the ciliary nerves, for the pain was confined to the eye and the cornea had remained anaesthetic, but to some rheumatic affection of the episcleral tissues, and that the pain was felt through the conjunctival nerves.

It should be admitted that both operation and after-treatment were of more moment in neurotomy than in enucleation. The operation of enucleation was simple, the after-treatment usually nothing; the patient could often re-sume his work in a couple of days. Neurotomy was more difficult and the after-treatment of more importance and longer, but it possessed more than corresponding advantages. Dr. Wadsworth had performed the operation in a somewhat different manner from that described by Dr. Williams. After division of the optic nerve, he had rotated the eye till its posterior surface was brought into view and he could satisfy himself by ocular inspection that all the ciliary nerves had been cut. Hemorrhage of any considerable amount he had seen little mention of in the cases reported abroad, and had found no inconvenience from it in his own cases. Considering the anatomical conditions, that Tenon's capsule with its prolongations backward to the apex of the orbit inclosed a lymph space between it and the sclera, that this space could be injected from the cranial cavity, the fluid even passing through the sclera along the sides of the vena vorticosae to the space between choroid and sclera without penetrating the orbital tissues, it seemed that hemorrhage into the orbital tissues could hardly occur unless Tenon's capsule had been wounded, the blood flowing into the tissues through the cut, or a vessel outside the capsule having been divided also. The first case in which he had done neurotomy was shown to the society more than a year ago. For three or four months the only change in the appearance of the eye was some atrophy of the iris; more change had taken place since, and now, fourteen months after the operation, the eye was slightly, but not markedly, smaller, the lower part of the cornea was cloudy, and a whitish membrane had formed across a large part of the pupil. The man was a boot-black, had worked steadily the past thirteen months, and had experienced not the slightest discomfort. It could not be doubted that in his condition he had been far better off than he would have been with an artificial eye, aside from the matter of expense. Another man operated on eleven months ago had been seen that day. He was a laborer, exposed to all weathers. The cornea was insensibile, and had retained its transparency perfectly.

¹ Augenkl. in Bern. Bericht über das Jahr 1878, S. 65.

² Jahresbericht über die Wirkksamkeit der fruher Ewers'schen Augenkl. im Jahre 1878, S. 16.

³ Vorträge aus dem Gesamtgebiete der Augenheilkunde, Zweites Heft, S. 104.

The power of resistance to injury which the eye possesses after neurotomy was well illustrated by a man who had staphyloma of the whole cornea. During the first few days after the operation there was a little superficial ulceration. Afterward the staphyloma increased, and the aqueous was evacuated several times by paracentesis. Three or four months after the neurotomy he again entered the City Hospital, in the medical wards, with Bright's disease, and at that time Dr. Williams saw him, and twice divided the cornea across nearly its whole width without the eye suffering.

An instance of the value of neurotomy in another direction was given by a case operated on by Dr. Wadsworth last summer. The patient had lost the sight of one eye by a blow three or four years ago. Since that time, as he said, he had been alternately able to work for three or four months, and then disabled three or four months by pain. Though the eye was somewhat shrunken and disfigured, though he had then had severe pain for some weeks and lost flesh and strength in consequence, neither he nor his wife would listen to the proposal of enucleation. They did accede to neurotomy. As a result of the previous inflammation, there were many adhesions between sclera and capsule, making the operation somewhat difficult, and there was so much swelling for a few days as to cause fear of orbital abscess. But the man kept his eye, and has been in good condition since.

Dr. HAY thought that the deeper wound behind the eye in the neurotomy was less safe than the comparatively open one left after enucleation, and referred to the circumstance that Tenon's capsule at the back part of the eye does not reach quite to the optic nerve, so that a way is left open through which blood or pus might pass to a deeper portion of the orbit.

Dr. F. P. SPRAGUE remarked that in regard to the cosmetic advantages of the operation of neurotomy they applied not only to the well-to-do classes, but especially to the laboring man, exposed to the contingencies of the weather. In such a person the irritating effects of out-door exposure on an empty orbit were apt to be a constant source of annoyance and discomfort, so much so that Mr. Critchett, of London, had advocated destroying the mucous surface of the orbit, and bringing the lids together in persons of this class; moreover, that artificial eyes, when carelessly worn, were liable to produce great irritation and even inflammation, and that such cases often presented themselves.

In reply to the objection of Dr. Derby as to the danger from hemorrhage, Dr. WILLIAMS said that though the bleeding was often so considerable as to press the globe forwards, and cause subsequent ecchymosis of the lids, yet there could not be a sufficient amount to create apprehension, inasmuch as the eyeball, held in place by the conjunctiva and by Tenon's capsule, would itself serve as a tampon to arrest the hemorrhage. In other cases, as for instance in a lady operated on two days before, the effusion was very considerable, while relief from pain and from the dimness of vision which had begun to be noticed in the other eye was observed on the day following the operation. Proliferation does not seem to have been observed in any other case than the one cited. As regards reunion of the divided nerves, it might be possible that the optics, having considerable size and rigidity, without much displacement of its cut extremities, should form a new connection, at least so far as its sheath was concerned; but the minute filaments of the ciliary

nerves, which are the conductors of the sympathetic irritation, would be extremely unlikely to reunite. Klein, of Vienna, in a work just published, speaks favorably of neurotomy.

OVARIOTOMY.

Dr. JOHN HOMANS said: At the last meeting of the society I showed three ovarian tumors, and as I was called away before the cases were commented on, your chairman has asked me to make a few remarks upon ovariectomy, merely as introductory to a discussion of the subject. First, let me say that the patient operated on a few days before I showed the specimens at our last meeting has recovered.

Ovariectomy is especially one of the greater operations of surgery in which success is almost sure to follow careful attention to necessary details; there is no operation where a good result may be so confidently expected; in many cases you can assure the patient that she will recover. What has made ovariectomy so successful within the last few years has been the antiseptic method of Lister grafted upon the most careful and perfect practice of every detail of cleanliness. Now in regard to the character of the tumor. The removal under the carbolic spray of a unilocular cyst without adhesions to the intestines and but a few to the omentum or abdominal wall is followed by speedy recovery. The more solid a tumor is and the more adherent, the less likely is the subsequent recovery, and this is perfectly natural; for a large, solid tumor requires a long incision, and extensive adhesions require long handling and more or less forcible treatment. Again, the physical state of the patient affects the chances of recovery. The more robust the patient is, the better she recovers,—that is my experience; the most rapid and striking recoveries that I have had have been in patients of this description. It is difficult, for me at least, to classify some of the almost solid cystic tumors of the ovary, that is, whether to call them cancerous or not, but there is a class of malignant tumors which I have removed three times. I refer to the papillomatous or "wart-like" ovarian tumor. These tumors usually burst through their enveloping cyst wall early in their career, and the cystic fluid poured out sets up an ascites, so that at the operation you have generally more ascitic than cystic fluid. These tumors stand up like cauliflower, and involve, sooner or later, both ovaries. Soon after recovery from ovariectomy, in one of these papillomatous cases, a new growth takes place in the other ovary and in the peritoneum and other organs, and the patient dies within six months. Such cases are spared much suffering, and sometimes enjoy a few weeks of health; however, as a general rule their recovery is not rapid, and their subsequent decline in health takes place before its reestablishment is completed. But little is said in the books to which I have had access, and yet I have met with three cases in twenty ovariectomies.

This operation should always be done under the spray; the vapor of carbolic acid seems to be entirely unmitigating to the peritoneum. Three years ago, in 1877, I first operated under the spray, and I am inclined to think that this was the first antiseptic ovariectomy in this part of the country. I always have the patient placed on a narrow board (eighteen inches wide), and I surround her with hot sand bags or hot-water bags, so as to keep her warm, instead of warming her up after she has become chilled from shock or loss

of blood. I like to have five good assistants and sometimes six, if many sponges are used. In my last operation we used forty sponges, and these were each wrung out four times. This was rather more than one man could do easily. There are two points to be observed in operating: one is to allow no blood nor cystic fluid to enter the abdominal cavity, and the other is to sponge out clean and dry before sewing up. No matter how much you may handle the bowels and other organs, you will do more harm by leaving a teaspoonful of blood or other fluid than by all your handling and rubbing. In regard to the treatment of the pedicle (that is, the tissue which connects the cyst with the uterus, consisting of the broad and round ligaments, the Fallopian tube, and the vessels and nerves nourishing the cyst), you must choose between the extra and intra peritoneal methods. The divided end of the pedicle may be held just outside the sewn-up abdominal wound by a clamp, a pin, or a ligature, or the uterine end of the pedicle may be tied and dropped back, or burnt off and dropped back. The most successful ovariotomist (Dr. Keith, of Edinburgh) has always used the actual cautery, and I presume that he does now. I have never dared to trust to it, but Dr. Keith has had seventy successive recoveries and only three deaths in his last hundred cases. I have almost always tied the pedicle in two halves and dropped it back. The only objection is that hemorrhage may begin and go on unknown to the nurse or surgeon from the slipping of some part of the pedicle out of one of the loops; this has happened to me once, but I do not think it will ever happen again. I generally constrict the pedicle with Dawson's clamp, which I have had made round and smooth, as you see, so that it cannot cut. I then perforate on the uterine side of the clamp, and thus secure the firm constriction of the pedicle. The intra-peritoneal treatment is followed by the most brilliant results, and does not twist nor pull upon the uterus, which the clamp is very apt to do. Adhesions may be torn with the fingers, or tied and then divided, or burnt off with Paquelin's cautery. It seems to make no difference whether you use silk or catgut in tying. As a rule, nothing is ever heard of the ligatures.

In regard to the treatment of patients before and after ovariotomy, it is best to feed them on simple gruel for a couple of days before the operation, so as to have the bowels out of the way, and to give a cathartic the night before the operation, and an enema just before. After the operation, give no food until flatus is passed per anum. This happens either on the second, third, or fourth day. Ice may be given freely, and stimulants and nourishment by the rectum, if required. I never advise a subcutaneous injection of morphia unless the pain is excessive and the case looks fatal; but little opium is generally desirable, sometimes none. The wound is not to be examined till the seventh day, and then is found thoroughly united, and you may remove all the sutures. Thrust and tympanites are the principal troubles, and these soon pass away.

Dr. LYMAN remarked that the changes which had taken place in less than twenty-five years with respect to ovariotomy were remarkable. In 1856 the whole number of operations which had been reported in the literature of the medical world did not exceed three hundred. Now one man alone in New England had done nearly that number, and in England Mr. Wells was approaching his one thousandth case. Then the mortality was over forty per cent., now it was

less than any of the capital operations, and bid fair soon, in the hands of Mr. Wells and Dr. Keith, to be no more than would follow the simplest operation of the dentist. At that time thirty per cent. of the operations were abandoned after being commenced on account of errors in diagnosis, or from adhesions; now errors in diagnosis were extremely rare, and adhesions were considered of little consequence, unless unusually extensive and complicated. At that time surgeons were nearly unanimous in condemning the operation, threatening not only professional ostracism, but even the interference of the grand jury, and the originator of the operation, if known at all beyond his home, was known only as an obscure backwoods surgeon; now the name of McDowell is honored throughout the world, and the profession in America has raised a monument to his memory, while surgeons everywhere are proclaiming their successes. In the history of surgery what operation has made such rapid strides in professional recognition, or what operation, even when most successful, gives equally good results to the sufferer? And it must be remembered that a successful ovariotomy restores the sufferer to perfect health. No crutch is required as after amputation, no artificial eye as after evulsion of that organ, but the wretched invalid is, as by a miracle, restored to life, with all her functions perfect for the duties of married life.

What is the cause of this rapid improvement in the results? At first, opinions were very diverse as to long and short incisions, an early or late removal of the cyst, etc., but all these things have gradually fallen back into the domain of ordinary surgical principles, and, when these are intelligently followed, do not probably affect the general result. The real answer seems to be that fatal results are not so much dependent on shock, hemorrhage, peritonitis, etc., as upon septicæmia, and since attention has been fixed more earnestly upon that, we may claim that the good results which follow the ovariotomy of to-day are due, first, to the excessively scrupulous care as to cleanliness of hands, instruments, bedding, and surroundings; second, the removal of every particle of clot or blood from the abdomen before closing the wound; and, third, the thorough use of carbolic spray and antiseptic dressings. Every surgeon has his own notions as to the management of adhesions, the use or not of drainage tubes, the method of dividing the pedicle, the use of this or that clamp, of the cautery, etc., but the really important factors for a successful issue may be considered with tolerable certainty to be the three above named.

Dr. WHEELER remarked that it was by no means the young and robust who made the most favorable cases for operation, and that the greatest care should be used in determining on the proper time for the performance of ovariotomy. He had used Dawson's clamp once only, and he found, practically, that if there were much tympanites the small end of the clamp acted as a wedge into the abdomen.

In conclusion, Dr. JOHN HOMANS said that Dawson's clamp was merely used temporarily to obtain firm compression while the ligatures were being applied. Dr. Homans also remarked that Dr. Keith was a doctor of medicine, not Mr. Keith.

—We are very glad to observe that *The Lancet* begins the new year with cut leaves, a good example which all journals should follow.

Recent Literature.

The Pathology and Treatment of Venereal Diseases.

By FREEMAN J. BUMSTEAD, M. D., LL. D., etc., etc. Fourth Edition, revised, enlarged, and in great part rewritten by the author and by ROBERT W. TAYLOR, M. D., etc. With one hundred and thirty-eight Wood-Cuts. Pp. 835. Philadelphia: Henry C. Lea. 1879.

Contemporaneous are the appearance of this magnificent treatise and the demise of its talented and industrious author; of twin birth the earliest reviews of the book and the obituaries of the workman. The best eulogy of the master hand is that which it has created, and of all moments that in which to pass away is the moment of victory, of the completion of a great labor admirably performed.

Each of the three previous editions, practical hand-books as well as scientific monographs, has ranked *facile princeps* among literary productions in the English language upon these topics. The present edition is a marked advance upon the preceding ones.

We say "these topics" advisedly, for the volume treats of "gonorrhœa and its complications," of the "chancre and its complications," and of "syphilis." The first subject appertains justly to genito-urinary surgery, the second to dermatology, while the last, included theoretically in dermatology, is practically as comprehensive almost as the science of medicine, if, indeed, it be not the chief fountain-head of the stream of physical ills inherited by the "heirs of all the ages." The writer admits that "in future it will be impossible to include venereal diseases in a single treatise." "Venereal diseases" are in fact not necessarily of venereal origin. The individual characteristics of a virus give rise to definite special results in the living tissues with which they are brought in contact, ignoring the means of transportation, whether it be the fang of a cur or the consecrated wafer of a Borgia. Neither etiologically nor pathologically do "venereal diseases" constitute a specialty in medical science.

Previous editions of this work, comprehensive, clear, and practical, have been the text-books upon the subjects of which they treated. But during the nine years which have elapsed since the publication of the third edition, many most valuable contributions have been made to the branches of knowledge therein considered, and these have been fully and thoroughly embodied in the edition before us. The reading matter has been increased nearly fifty per cent. Every chapter has been revised, and improvement has been made in the order of subjects by a more logically scientific rearrangement of the topics treated, some chapters being extended and developed, while eleven new ones have been created. Among them are found such as treat of affections until recently unknown, or of tissues formerly supposed to be exempt from the ravages of syphilis, and also such as introduce for purposes of differential diagnosis various diseases of the skin or of the serotol organs. The chapter upon the *syphilides*, more properly syphilodermata, that upon nervous lesions, and especially the one upon "hereditary syphilis," in which subject of late great progress in knowledge has been made, are worthy of special consideration.

We trust that it may not seem in bad taste to call attention, for the sake of what we believe to be truth,

to the introductory chapter, upon the History of Venereal Diseases, wherein a "distinct, specific virus" is denied as appertaining to the so-called chancreoid. A dualism based upon this tenet is doomed, it seems to us, to extinction, while the fact that sores not to be distinguished from each other clinically are yet totally distinct in nature, each one being inoculable upon healthy persons, but one being followed by constitutional symptoms, while the other is not so followed, is patent to every observer. We may inoculate pus with or without the virus of syphilis, or the latter with or without pus, and sufficient stress has never yet been laid upon the anatomical structure of that part of the integumental tissue, follicle or otherwise, which has been invaded.

In these days of spots on the sun a review is hardly complete unless some fault is found, and that it is difficult to do in the present case. Possibly, if we strain a point, we may say that in certain cases the diction is somewhat more Anglo-Saxon than picked; yet even this, if an error, is a rare one, and in the right direction.

In accordance with the tenets entertained ever since the torture of Galileo, the metric system has been employed. In abbreviations of the titles of periodicals the method of the *Index Medicus* has been followed. The errata are few. The illustrations are increased, and a list of them has been added. Thanks to the labors of Dr. C. H. Knight, an excellent and complete index is appended to the work. Paper, typography, proof-reading, and binding do credit to the well-known firm by which the volume is published.

The treatise has lost nothing by the addition of the advanced views, the active brain, and the industrious pen of the new co-editor, whose aim has been, through "bringing the volume up to date, by including all affections thus far known in the shortest and clearest manner, to present a book worthy of the American medical profession."

E. W.

With General Grant in the East. By JOHN M. KEATING. Philadelphia: J. B. Lippincott & Co. 1879.

The attention of the profession is called to this entertaining little book, originally published as a series of letters to the *Philadelphia Evening Telegraph* while its writer was journeying around the world. Dr. Keating is a quick and accurate observer, and his literary style is fluent and vivacious. He accompanied General Grant's party round the world as private physician to Ex-Secretary of the Navy Borie, yet his professional capacity does not often appear in the text of the book under consideration. A notable exception occurs on page 122. On pages 26 and 27 we find valuable information on the disadvantages of the climate of Egypt for consumptives, which, like the disadvantages of Southern California, are too often overlooked. In his journey the author saw many beautiful sights, but his enthusiasm seems to have reached its height on viewing the Taj Mahal at Agra. The book is interesting throughout.

PAX.

— New Jersey. 1879. Marriage Contract; Breach; Impotent Person. Opinion by Beasley, C. J. A promise to marry made by a person physically and incurably impotent is contrary to the statutory policy of the State, and its breach will not constitute a cause of action.

Medical and Surgical Journal.

THURSDAY, JANUARY 22, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Osgood and Company, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to Houghton, Osgood and Company, Boston, Mass.

HARVARD UNIVERSITY AND FEMALE PHYSICIANS.

THE annual report of the president and treasurer of Harvard University was presented to the overseers at a late meeting. In regard to the Medical School, we observe that its prosperity continues and increases. In 1878-79 the number of students increased ten per cent., and the excess of receipts over expenditures was \$9540.07, although each of the clinical instructors received an honorarium, which was a new charge upon the school. The number of students who possess literary or scientific degrees has doubled in ten years, and now amounts to forty-eight per cent. of the whole number.

President Eliot reviews in detail the movement for the admission of women to the Medical School in connection with Miss Hovey's proposal, which, as our readers may remember, was an offer to give the sum of ten thousand dollars to the school on condition that women should be admitted to its advantages "on equal terms with men," and he concludes as follows: "The passage of this vote (a vote of the overseers declining Miss Hovey's offer) disposed of the subject so far as the offer of Miss Hovey was concerned, but the prolonged discussion was, nevertheless, not without fruit. It is *obvious*¹ that both the governing boards are in favor of giving medical education to women in the university under suitable restrictions, and it is also apparent that the reasons given by the faculty for not admitting women to the school are *temporary* in their nature. Since these transactions, the councilors of the Massachusetts Medical Society have taken action which goes far to prove that the *majority* of the medical profession recognize the fact that there is a legitimate demand and an appropriate field of work for well-educated female physicians. At their meeting of October 1, 1879, it was voted, yeas forty-eight, nays thirty-two: 'That the councilors instruct the censors of the society to admit females to examination as candidates for admission to fellowship.' This action cannot but suggest the inquiry whether it be expedient that Harvard University should make no provision for educating a class of persons who are *admissible* as members of so ancient and respectable a professional body as the Massachusetts Medical Society."

If our information serves us correctly, — and we have taken some pains to follow the discussion of this subject, — we must permit ourselves to say that President Eliot's sympathies and well-known love of progress and innovation have apparently led him to give a

¹ The italics are ours.

coloring to his language which the facts alone would hardly justify. When saying "it is obvious that both the governing boards are in favor of giving medical education to women in the university under suitable restrictions," we suppose the president to have in mind a resolution to that effect which was introduced by himself without previous notice, and passed, without discussion, by a vote of sixteen to ten, at the close of a meeting at which it had previously been resolved by a vote of seventeen to seven that it was inexpedient to accept Miss Hovey's proposal.

When the managers of political meetings secure the passage of pet resolutions in this manner, they are said to "spring" them upon their victims. As was stated in the editorial in our issue of June 5, 1879, we have good reasons for supposing that several members of the board of overseers did not at the moment appreciate the inconsistent or hostile attitude of this eleventh-hour resolution, and we believe they did not anticipate the use to be made of it; under these circumstances the word "obvious" seems ill chosen. Again, it may perhaps, to some minds, be "apparent that the reasons given by the faculty for not admitting women to the school are temporary in their nature," but the language of the following resolution, passed by the medical faculty, after full discussion, by a vote of fourteen to four, is plain: "Resolved, that it is not advisable to open the course of study at the Medical School to women."

It is at least problematical how far the action of the councilors of the state society, in regard to the admission of women, goes to prove anything, but it is certain that no woman has as yet been examined for admission, and, as has been pointed out, it is very doubtful whether the councilors *can* represent the society in this matter. Moreover, of those who voted in the affirmative, some did so on different grounds from those suggested in the remarks quoted above.

The practice of medicine by women will doubtless find its own level, whatever that may be, and we see no occasion for dwelling further on the subject at present; but we do deprecate the treatment of such a question in so serious a document as the annual report of Harvard University, by the chief officer of the university, in a manner which suggests to the mind of the reader the word — jesuitical.

THE TRANSACTIONS OF THE AMERICAN MEDICAL ASSOCIATION. VOLUME XXX., 1879.

THIS volume is the result of the meeting of the American Medical Association at Atlanta, Georgia, last May, and presents itself with an imposing bulk of over one thousand pages, and an equally imposing array of topics treated. The first hundred and twenty-five pages are consumed by the minutes of the preceding meeting, the reports of the officers of the association, and the address of the president. These are followed by the minutes of the five different sections, the addresses in each section, and no less than thirty-six different papers on as many different subjects in the various sections. It is not necessary to consult the treasurer's report to be persuaded that the ex-

penses of the association for printing must be large. Among these thirty-six papers there are certainly some of much interest and value; but a number of others, though adding to the size of the volume, do not increase its worth. A more rigid censorship of the material for publication would be a gain at once to the treasury of the association and to those who become possessed of its printed transactions. From the report of the committee appointed to confer with the superintendent of the Signal Service Bureau of the United States government, relative to the addition of daily observations concerning the electric and ozonic conditions of the atmosphere to the items at present included in the meteorological records made at the several stations in that service, we observe that, whilst the superintendent manifested a disposition to render the work of the bureau as useful as possible in the advancement of medical investigations, yet he was not willing to attempt the proposed additional records until the association or its committee could point out more definitely the best methods of making the proposed observations and the best instruments for the purpose. The suggestions of this committee were adopted, and it was continued, the name of Dr. H. O. Marcy being substituted for that of Dr. Billings, with instructions to pursue the objects suggested by General Meyer. The field which this committee has before it is very extensive, and we shall watch with interest its progress. The volume ends with the prize essay of the year, a paper by Dr. Alvan McLane Hamilton, of New York, entitled *A Consideration of Certain Forms of Primary and (Local) Secondary Degeneration of the Lateral Columns of the Spinal Cord, with Especial Reference to an Infantile Rare Form.*

THE NEW HAMPSHIRE MEDICAL SOCIETY.

THE New Hampshire Medical Society has lately published its proceedings for the past year in a full and interesting volume. At the annual meeting in June, the retiring president, Dr. Alonzo F. Carr, after congratulating the society upon its eighty-ninth anniversary, referred to the growing knowledge on the part of the public in matters of health and disease, and the consequent diminution in the number of irregular practitioners. Forty years ago, Dr. Carr said, "the burden of many papers read before this society was some scheme for the suppression of quackery, the authors not recognizing the fact that they were pursuing the only course possible to suppress it by educating themselves up to a higher standard of excellence; so that the result of treatment as directed by the well-trained physician, compared with the result of the treatment of the untrained quack, literally left the latter without a foot-hold in the community." This foot-hold, however, does not appear to be so easily lost in all our communities, even in those which maintain a relatively high educational standard. It is not necessary to inquire into the causes of such perversity, but it may well be questioned whether the public powers of observation are sufficiently keen to

counterbalance the innate credulity and hankering after the miraculous of those who, it is thought, make a mild form of protection desirable both for us and themselves. The question of a medical license law for Massachusetts is assuming a tangible form under the auspices of the Social Science Association, and we shall have occasion to refer to it again.

Dr. Carr concluded his address with some interesting remarks on fractures of the lower end of the radius, in the treatment of which the splint invented by him has been so extensively adopted.

Dr. George B. Twitchell, in a paper on Medical Ethics, points out in poetical language the hardships which the attending physician must still undergo at the hands of the unscrupulous consultant and other violators of the unwritten code. He also calls attention to the scandalous practice of advertising, directly or indirectly, in the public prints, and to the degrading freedom with which many "noted physicians" lend their names for the furtherance of commercial enterprises. We are happy to be able to say in this connection that no elixir or mineral water has yet appeared capable of exciting the enthusiasm or relaxing the self-respect of our Nestors to that extent.

Dr. Odlin portrayed in pleasant terms the sorrows and the joys of The Country Doctor, and was followed by Dr. D. S. Adams, with a paper on the Differential Diagnosis of Mammary Tumors, and by Drs. Wheeler and Whittier with reports on Surgery and Gynecology.

A valuable historical paper on Dover Physicians, giving a sketch of every regular physician who had practiced in Dover from 1631 to the present time, seventy-five in number, was contributed by Dr. John Randolph Ham.

A short paper by Dr. L. G. Hill points out the frequent inconsistencies and worthlessness of medical testimony under the present mode of summoning witnesses, and the discredit which is brought upon the profession thereby, both in the eyes of the court and of the public.

An Epidemic of Diphtheria in the village of Groveton is described by Dr. Watson. At the time of the outbreak there was no diphtheria in Groveton, or in any of the surrounding towns. The first twenty-five cases were in children who attended the same school, but whose homes were far apart. Twenty-two of them developed the disease within ninety-six hours, and subsequently there were one hundred and fourteen cases in all. Dr. Watson treated one hundred and twelve cases with thirteen fatal results. Two of these, however, had previously been under homœopathic treatment, and did not long survive; this fact, the author naïvely states, is mentioned, not to disparage the treatment of others and compliment his own, but to complete the record. Careful hygiene, tincture of the chloride of iron in full and frequent doses, alimentation, and spraying with lime-water and carbolic acid were the chief agents in treatment. The author did not perceive much benefit from the use of alcohol. The epidemic began in May. No cases of simple tonsillitis were called diphtheria. The common source

of infection was thought unquestionably to be a filthy and ill-drained school-house.

The transactions conclude with a lecture by Professor Oliver P. Hubbard, on the Origin of the New Hampshire Medical Institution at Dartmouth College.

We are glad to observe that Dr. M. C. Lathrop, who represented the society, as delegate, at the meeting of the Connecticut State Medical Society, says in his report that a good résumé of the president's address, and of the different papers may be seen in the Boston Medical and Surgical Journal, "the publication which most worthily, and with justice, lays first claim to the patronage of every New England practitioner." This view accords so nearly with our own that we cannot refrain from mentioning it.

Dr. Pray, of Dover, was elected president, and Dr. Conn, of Concord, formerly secretary, vice-president.

MEDICAL NOTES.

— Dr. J. Winthrop Taylor, who died in Boston on the 19th inst., was born in New York, August 19, 1817. He graduated at Princeton College, and afterward pursued his medical studies at the University of Pennsylvania. Immediately afterward he entered the navy — March 7, 1838 — and from that time forward saw more than thirty years of active duty, serving through the Mexican war and the war of the rebellion. He accompanied the expedition sent to bring the filibuster, General Walker, away from Nicaragua, and commanded in person the detail which conducted the prisoner by a long and perilous journey to the coast. Few men in the navy saw more sea service, he rising rapidly through the various grades until 1852, when he was made a surgeon, with the rank of commander. He was in the midst of the severest battles through the war, was surgeon of the Pensacola when she ran the blockade of rebel forts along the Potomac River, and on the same ship accompanied Farragut in his memorable passage of the forts on the Mississippi, and assisted in the capture of New Orleans. Last year Dr. Taylor was stationed at Washington, with the rank of surgeon-general, and in October was placed on the retired list, he having reached the age of sixty-two, required by the regulations of the service. Previous to his appointment as surgeon-general, Dr. Taylor lived for many years in Boston, having been repeatedly attached to the rendezvous and the receiving ship at Charlestown, and to the naval hospital at Chelsea.

— Dr. Swift, port physician, having resigned, the board of health has promoted Dr. Woodbury, the assistant physician at the quarantine, who will now perform the duties heretofore devolving on Dr. Swift.

— *Appleton's Journal* contains a calculation by Berthelot, the eminent chemist, of the number of combinations which may be made of acids with certain alcohols. He says, "If you give each compound a name, and then print one hundred lines on a page, and make volumes of one thousand pages, and place one

million volumes in a library, you will want fourteen thousand libraries to complete your catalogue."

— In the *Practitioner* for August, Dr. Rabagliati claims that in many instances he has been able to check incipient pneumonia, peritonitis, pleurisy, and tonsillitis, especially in children, by administering small doses of aconite every ten or fifteen minutes, until a fall of pulse and temperature, moisture of the skin, and sleep have been induced.

— At the meeting of the Medical Society of Munich, in October, Professor Rüdinger exhibited some remarkable results of his manipulations of the human body by frozen sections. Eight of these are carried longitudinally from the crown of the head to the sacral region, and are so connected that they can be opened or closed like the leaves of a book. When exposed, the fourteen surfaces exhibit in their natural form and color all the anatomical details of the various organs. "A most interesting spectacle it was to have the body in an erect position, and open and shut any of these sections." The society was excited to enthusiasm by the exhibition. Professor Ziemssen designated it a "European unicorn."

— In the Transactions of the College of Physicians, of Philadelphia, volume iv., Dr. Bridges reports, on behalf of Dr. John L. Atlee, of Lancaster, Pa., a "remarkable case of congenital ventral gestation, the subject being a girl six years old, who recovered after the discharge of the fetal mass from her abdomen, and lived seventeen years."

— According to the *Medicinische Wochenschrift*, there are this year only one hundred and thirteen females in the medical school of St. Petersburg, against two hundred female students in the same institution last year.

— The Heliotype Printing Company lost, by the recent fire, the materials collected during its existence of seven years. Twenty-five thousand negatives, some forty to fifty specially designed hand and power presses, twenty or thirty lenses and cameras of all the best known makers, carefully devised appliances, tools, and fixtures for the various processes employed, original engravings, works of art, designs, drawings, in fact, every implement that went to make up its working whole was destroyed. The process of heliotype printing was brought to this country by the enterprise of Mr. James R. Osgood, who secured the patents for the United States at the end of the year 1872, when he also secured the services of the inventor, Mr. Ernest Edwards, to superintend their working. The first pictures offered for sale were views of the burnt district, caused by the fire of 1872, and a map of the same. The first pictures now produced by the company in its new printing office are views of its own burnt district. The success of the company is well known to the business community, and the scope of their work has been increasing year by year, until, at present, there is a permanent demand for their goods among all classes of citizens, professional and otherwise. The company has leased the building Nos. 124-126 Pearl Street, and the rooms are being rapidly fitted up for their special purposes.

—The *British Medical Journal* writes as follows: "Dr. J. Milner Fothergill, writing to the *Philadelphian Medical Times*, makes the following extraordinary statement: 'In the United States of America, a doctor holds at least a respectable social status. In this country, with few exceptions, his position is anomalous, and his wife is a social pariah.' Under what singular inspiration this amiable physician could have penned so extraordinary a paragraph for the information of our medical consins, it is difficult to imagine. We hope that Dr. Fothergill considers himself at least one of the exceptions, and that he does not find his position particularly anomalous. On the conjugal question, he is, we believe, a bachelor; and perhaps not, therefore, altogether in a position to estimate the social status of other men's wives; but where and how he has arrived at the conclusion that the wives of his medical friends and colleagues are to be designated by this uncomplimentary Indian term is a mystery which perhaps he alone can clear up. At any rate, as Dr. Fothergill is a writer who enjoys some credit both here and abroad, it is as well to notice the singular statement to which he lends the weight of his reputation as a London correspondent of American papers, although we are sorry to say that, in doing so, we can only characterize it as a statement which is utterly absurd and without a shadow of foundation. It must have been written as Dr. Fothergill's idea of a 'goak'; but, from the notices we have seen of it abroad, it is evidently supposed that he was serious when he wrote it. A gentleman who professes to represent his country abroad should be a little more careful in his statements."

—Professor Erb has been called from Heidelberg to Leipsic. — Professor Hebra is still sick. Kaposi temporarily takes his place in the school.

—Dr. E. L. Peck, a writer of many interesting letters to the JOURNAL from Europe, has now established himself in New York, and in addition to two large dispensary services for diseases of the eye and ear he has recently received the appointment of visiting surgeon to the ophthalmic wards of Charity Hospital, Blackwell's Island. Dr. Peck's abilities and thorough education well qualify him for the position.

—The following are the conclusions at which Mr. Vincent Richards arrived with regard to opium eating in India, as given in the *Indian Medical Gazette*: (1.) That opium is taken habitually by about eight to ten per cent. of the adult population of Balasore, and that the average daily allowance for a man is seven grains, and for a woman five grains. (2.) That moderation is the rule. (3.) That moderate doses include from two to sixteen grains per diem, according to circumstances. (4.) That opium-eating is much more common in unhealthy than in healthy localities, even though they are situated in the same district. (5.) That the drug is sometimes taken in very large doses—thirty grains and upwards—without producing any very serious ill-effects, much depending on the constitution of the individual and his habituation to its use. (6.) That whatever the effects of the excessive use of the drug may be, when taken in moder-

ation it is positively beneficial where such diseases as fever, elephantiasis, rheumatism, etc., are present, and when food is scarce. (7.) That the effects of even the most excessive use of opium are harmless, both to the individual and to society, compared to the excessive use of alcohol.

The *Quarterly Journal of Inebriety* thinks that these conclusions are not confirmed by the experience of investigators in this country or Europe, and sound very much like a defense of opium.

—The same journal states that a curious case has been contested in New Orleans, of a gentleman who from misfortune began to drink, and finally, after an attack of delirium tremens, died suddenly. The physician gave a certificate of albuminuria, and the insurance company contested it on the ground of intemperance. At the time of being insured the patient was temperate, but after, from misfortune, he drank hard, and died. The question of the disease of inebriety will be a prominent feature of the case.

NEW YORK.

—General Patrick, the New York State Cattle Commissioner, has made his annual report for the year 1879 to Governor Cornell. It is a condensed history of the contagious pleuro-pneumonia that prevailed among horned cattle during the year. The report begins with an account of the embargo laid upon the importation of American cattle into England by the British government in consequence of the prevalence of pleuro-pneumonia among some stock in this country. All American cattle were slaughtered upon being landed at Liverpool. This action of the British authorities led Governor Robinson to appoint Prof. James Law, of Cornell University, a commissioner to investigate the disease in Kings and Queens counties, where it chiefly prevailed. Professor Law subsequently reported that the disease was of a very dangerous character. The legislature promptly appropriated ten thousand dollars to stamp it out. Governor Robinson then appointed General Patrick as his agent for the expenditure of the money. General Patrick at once inspected the infected stables on Long Island, and ordered the animals in many of them quarantined. Many stables in Brooklyn were inspected, and much disease was found among the animals of the city. Infected animals were condemned, their value appraised, and they were then slaughtered. Out of eight hundred and seventy-nine cows quarantined at Blissville on February 12, 1879, all except one hundred and forty-six were, by March 10th following, either slaughtered for beef, or condemned and slaughtered. British cattle that arrived at the port of New York were also quarantined. A few cattle that had been taken to Dutchess County were followed, placed in quarantine, and the stables disinfected. Through the spring months systematic inspections of cattle-yards and stables were made in New York, Brooklyn, and in Queens County. A large number of cattle that were found diseased were slaughtered. All railroads were prohibited from unloading any cattle in New York and Brooklyn except at designated places. In

May the cattle plague was discovered among the herds on the "Great Montaux Pasturage," in Suffolk County. General Patrick went to the range and had the diseased animals killed. This stamped out the disease. It has been almost driven from New York and Brooklyn, but still exists in Blissville. The disease has also been subdued in Putnam County, where it was discovered among the herds in October last.

—The New York chamber of commerce has adopted the following resolutions:—

Whereas, a national board of health was last year chartered by Congress, for the purpose of promoting the sanitary welfare of the whole country, and especially of those sections which are unable to take adequate measures for protection against the ravages of disease; and whereas the work already done by this board has been of great value, and has demonstrated that a wide field of usefulness is open to it, and that there is urgent need of a permanent national organization of this kind; and whereas, at a recent conference between the National Academy of Sciences and the National Board of Health, a plan for increasing the usefulness and efficiency of the latter was agreed upon, and additional legislation is to be asked from Congress; therefore,

Resolved, that in the opinion of this chamber it is important that the National Board of Health should be maintained, and its usefulness developed in the manner indicated by the National Academy of Sciences.

CHICAGO.

—The *concours* for the lectureship on gynaecology in Rush College spring course has occupied the two evenings of January 6th and 7th. There were six contestants: Dr. E. B. Ellis, of Galesburg, Ill., who lectured on abscess of the vulvo-vaginal glands; Dr. D. T. Nelson, of Chicago, who lectured on sympathetic disturbances; Dr. W. L. Ransom, of Roscoe, Ill., who lectured on membranous dysmenorrhoea; Dr. D. C. Camp, of Chicago, lecturing on peritonitis; Dr. A. J. Stone, of St. Paul, Minn., lecturing on sarcoma uteri; and Dr. R. Stansbury Sutton, of Pittsburgh, who discussed the subject of dermoid cysts. The choice clearly lay between Drs. Nelson, Stone, and Sutton. Dr. Stone desired, if elected, to remain a resident of St. Paul. The college authorities would not consent to the appointment of a man who would not be a resident of Chicago. The place was offered to Dr. Sutton, on condition that he comes to Chicago to reside.

—President J. Adams Allen, professor of the practice of medicine, of Rush College, in accordance with an arrangement made months ago, leaves for New York on the 13th inst., to sail for Europe on the 17th inst., by the steamer Germania. He will remain abroad several months in quest of health and in professional observation. Overwork in the duties of his chair, in professional labor, and in carrying the burdens of some of his colleagues, who were abroad last year, have made more necessary this well-earned respite, which has been long contemplated. The course on practice of medicine will be completed by the lecturer on that branch in the spring course.

—Considerable public indignation has been occasioned by the escape and flight from the small-pox hospital recently of a woman who had been sent there by mistake, and who made loud complaints of the bad management of the institution. The woman had nursed her husband in a genuine case of variola, and nine days thereafter was taken sick and had a few pustules about the face. Very naturally she was supposed to have the disease. Now it appears that the diagnosis was mistaken. Her stories about the bad condition of the hospital were exaggerated, but those about the management by the parties in charge, it appears, were well founded. The authorities have made the best amends they could by taking steps to remove the superintendent. What is amazing and scandalous is that the city officials should have needed such an outrage as the one that has occurred to acquaint them with the fact that this institution, which, as patients of all classes are forced to go there, more than any other should be above reproach and past criticism, has been conducted in an inefficient manner, if not with brutality.

—Prof. D. W. Graham has returned from his sojourn in the South, and resumed his practice. He comes back apparently in perfect health.

ST. LOUIS.

—The annual election of officers of the St. Louis Medical Society was held on the 3d inst., resulting as follows: president, G. M. B. Maughs, M. D.; vice-president, F. W. Wesseler, M. D.; recording secretary, M. H. Post, M. D.; corresponding secretary, J. R. Lemon, M. D.; treasurer, W. E. Fischel.

—A urinary calculus weighing one pound six ounces avoirdupois was removed by Dr. John Hodgen on the 3d inst. The stone was nearly spherical, and measured eleven and a half inches in circumference, and about four inches in diameter. The removal was accomplished by the supra-public operation, and the calculus was necessarily broken. The patient was sixty-two years old, and up to within a few days had been in the habit of walking from two to four miles daily. Fifteen years ago he had two stones removed from his bladder by Dr. C. A. Pope, and from that time till the present has enjoyed remarkably good health for a man of his years, except for some vesical irritation, and, during the last two years, incontinence of urine. Before the operation the stone could be distinctly felt as a hard tumor in the hypogastrium. The stone is composed chiefly of phosphates. On the 6th there were some evidences of inflammation.

—The Transactions of the Medical Association of the State of Missouri, 1879, have just come from the press. They make a book of 143 pages, and of very good appearance. They comprise a number of valuable articles. One, upon two cases of false hypertrophy of the muscles, by Dr. A. J. Steele, is particularly interesting on account of the rarity of the disease of which it treats. This month has also brought from the press the first volume of the Proceedings of the St. Louis Medical Society, extending from March 2,

1878, to December 28, 1878. Both of these publications are illustrated.

LONDON.

—The *London Lancet*, in an article entitled *Sisterhoods*, speaks as follows:—

"Since it became the fashion to hand over the nursing of hospitals to associations of ladies whose bond of union is something outside the institution which they are called upon to serve, we have frequently been edited by squabbles between the ladies and those to whom they should be subordinate. These ladies often enter upon their duties with the conviction that they are conferring a favor upon the hospital, and they imagine that the obligation is all on one side, notwithstanding that the sums paid by hospital committees to the various associations with which the ladies are connected are in most cases greater than those previously paid to the ordinary nurses.

"We cannot unreservedly subscribe to the popular belief that nursing (that is, professional nursing) is an occupation which is at all suited to ladies who have been delicately brought up, and we feel sure that the lady who is ready to perform all those disagreeable duties which are necessary (let us say) for the prevention of bed-sores, must be a rarity, although we admit that such have been and are occasionally found. Such work is, we feel sure, better intrusted to strong, properly trained women of the lower class, who have been accustomed to dirty work from their youth up, and who are never squeamish over their duties. That a governess should be looked down upon, while a lady-nurse is regarded as a heroine, is an anomaly due to a fashion which, like other fashions, will have its day. It is a notorious fact that nurses dislike working under sisterhoods, because promotion into the higher ranks of the profession thereby becomes impossible, and nurses of experience invariably cut themselves adrift for the purpose of gaining something like independence and advancement."

—From the *Lancet*, December 25th, we learn that on the 11th inst. Mr. Berkeley Hill operated for vesico-vaginal fistula in University College Hospital, while the vagina was lighted up by Mr. Coxeter's application of the glowing platinum wire. The apparatus consisted of a fine wire twisted into a small knot. Through this knot was sent a continuous galvanic current, strong enough to maintain the wire at a white heat. The wire was inclosed in a glass chamber, which was itself also inclosed in another glass cover. Through the space between the glasses a current of water was allowed to flow, in order to preserve a low temperature round the light. The afternoon, which was dark and foggy, afforded a good opportunity of testing this plan of lighting up deep interiors, and the illumination was completely successful. A strong light was maintained for more than an hour close to the margins of the fissure without impeding the manipulations of the operator.

MEDICO-LEGAL.

— "At a recent meeting of the Medico-Legal Society of New York," says the *Chicago Medical Gaz-*

ette, "Mr. Amos G. Hull, in connection with the subject of malpractice, then under discussion, suggested two very important points by which physicians might in most cases avoid the disagreeable consequences of a prosecution. The first was, that as soon as they are satisfied, upon a careful examination of the case, that they have made a mistake, they should go and compromise with the aggrieved parties, and propose to do what is just and fair. The second was, that if a surgeon is threatened with a suit, and is satisfied that his practice has been correct, and he is guilty of no negligence or malpractice, he should bid defiance at all hazards to his adversary. He should immediately, when threatened with a suit, seek an honest, respectable, judicial forum, and prosecute for the collection of his bill. The patient would be legally bound to set up negligence or malpractice as a defense to the bill. If he did not, and judgment was recovered, that judgment would be forever a bar to the recovery by the patient for any malpractice, for the judge will hold that he had no such defense. If he had, he should have set it up then and there, or forever hold his peace."

—Supreme Court of Wisconsin: Case of Bastardy; Doubt as to Parentage. The Attorney General,* for defendant in error. *Orton, J.*, in delivering the opinion of the court, said: The testimony of Ann E. Swagger, the prosecutrix, is positive that her last menstruation was the first of September; that she had sexual intercourse with the defendant about two weeks thereafter, and with one C. Green last, about two weeks after that; that her child was born the 25th of May; and that the defendant is its father. In such cases the paternity of the child is the main and material fact to be found by the jury, and this fact the jury must find beyond a reasonable doubt. Whatever the probabilities may be, from this evidence, that pregnancy resulted from the first act of sexual intercourse, which was with the defendant, because of its being the nearest the termination of the period of menstruation, and of the longer time before the birth of the child, yet they are mere probabilities, and, by the best medical authorities, very questionable, and by no means without reasonable doubt.

The prosecutrix having had sexual connection with two persons within so short a time, it was impossible for her to testify which act produced pregnancy, and which person is the father of the child. In view of these undisputed facts and of the most creditable authorities, the jury could not have found the defendant guilty beyond a reasonable doubt. Physiological speculations, natural probabilities, or merely probable cause are quite insufficient upon the trial to establish the fact of paternity in such a case. There must be, from the very nature of such evidence, great and certainly very reasonable doubt as to this main fact. It is urged that if this is to be the rule a conviction can never be attained when more than one person has had sexual intercourse with the complainant about the same time. This consequence of the rule is far less important and serious than the wrong and injustice of a conviction upon insufficient evidence. In such a

case the question is not whether the defendant is guilty of having had illicit intercourse with the complainant, but whether by such intercourse the child was begotten, and this fact must be found beyond a reasonable doubt. This being the true legal rule, the consequence of its strict observance by courts and juries is not to be considered, except in changing or abolishing the rule itself; but while the rule exists the consequences will not be presumed to be wrong or mischievous, but rather right and just. Reversed and remanded.

Correspondence.

THE SENSIBILITY OF ARTICULAR SURFACES.

MR. EDITOR. — I wish through your pages to appeal to your surgical readers for information concerning the sensibility of articular surfaces. If any surgeon who may happen to read these lines meets with a case where, by accident, a joint has been laid open, or where an operation has involved the denudation of healthy articular cartilage, he will greatly oblige me by testing the sensibility of the cartilage in three ways, and either publishing the result in the JOURNAL, or communicating it to me by letter.

First, test the sensibility by the compass points, and find out the minimum distance at which they are felt as two. Second, pass the finger, or some hard, smooth body like the back or handle of a scalpel, over the surface, and see whether, in case the surface be, for example, the distal end of a proximal phalanx, the patient does or does not feel as if the next phalanx is being flexed upon the one in question. Thirdly, I would suggest that if the last experiment succeeds one side of the articular surface should be firmly pressed, with the view of ascertaining whether this treatment suggests to the patient that the succeeding parts of the member are being forcibly bent towards that side. I suppose we can hardly hope for opportunities for such observations on large joints, the opening of which would, if accidental, cause shock, and if operative require ether; but surely surgeons in busy practice must frequently see finger and toe joints laid bare with the patient's consciousness undisturbed.

The scientific interest of the question is this: The consciousness we have at any time of the position of our own members has always been rather a puzzle. Most observers have ended by concluding afferent sensations from the joints to be its source. This conclusion has been reached, however, not so much by direct evidence as by way of exclusion; that is to say, pathological cases have been successively adduced in which the consciousness of position remained unmodified, though feelings of innervation, feelings of muscular contraction, and cutaneous feelings were each in turn abolished. Only within a few months has Lewinski brought forward something like direct proof.¹ He found a patient who felt when he stood as if he were knock-kneed in his anæsthetic leg. When he lay down the illusion disappeared. Lewinski thought it might be due to greater anæsthesia medially than laterally of the surfaces of the knee-joint. This would produce, when the surfaces were pressed together by his weight in standing, the feeling that the lateral edges of the joint

were in forced contact, whilst the medial edges hardly touched, — a state of things which might be brought about in a knock-kneed position. Lewinski then found in patients with semi-anæsthetic feet that when he bent the toes passively, and at the same time exerted traction, the patients were not aware into what position he had bent their toes. When, on the contrary, he pressed the toe which he was bending against the foot, instead of drawing it out, they were fully aware of the extent of its motion.

Possibly some of your readers may be able to refer me to published observations of which I am ignorant. If these lines have the effect of arousing the interest of any one who will communicate his observations, I shall feel greatly indebted, for the matter is connected with important theoretic consequences.

I am, with respect, yours truly,

WILLIAM JAMES, M. D.,
Assistant Professor of Physiology.

HARVARD COLLEGE, CAMBRIDGE, MASS.

THE NATIONAL BOARD OF HEALTH.

MR. EDITOR. — In reference to the reply to my letter about the National Board of Health,² please let me say this: My statements in regard to the part Dr. Woodworth took in promoting the success of the Public Health Association, and especially of its meeting at Richmond in 1878, are true, and I reassert them. The facts were given me not by one, but by several members of that association. Dr. Woodworth did his best to prevent the organization of the National Board of Health in its present form, but not of a National Board of Health. The statement of your correspondent is misleading.

The assertion that all the power of the board has been virtually in one man is essentially true. The fact is not insulting to the members of the board, but is an unfortunate fault in its constitution. Its powers must necessarily be delegated. The insinuations of intrigue in regard to the refrigerating ship were of the vaguest kind, and the writer lays no emphasis upon anything except the essential absurdity of the scheme. Distinct charges in this direction, with offers of proof, have been made, we believe, in *The Nautical Gazette*, an able and reputable journal of this city.

The Marine Hospital Service, with which I have no connection whatever, does not, so far as I know, desire to assume the powers and duties of the National Board of Health. The accusation is unwarranted certainly by any action or expression of the present surgeon-general, whatever may have been the views of his predecessor, and your correspondent falls into the fault of which he accuses me in making the charge.

The statements made in my previous letter were all made with care. I had then, and still have, every reason to believe them to be true. Dr. Folsom has simply denied the truth of my statements, and I have reasserted them. This is a profitless form of argument; but the pages of a medical journal cannot be filled with elaborate testimony *pro* and *con*.

I attack no person, but only an organization, and therefore do not feel obliged to sign my name.

NEW YORK, December 31, 1879.

THE PILLS OF POWER.

It was the Baron of Mucklebille,
His looks were sad and sour;
Come hither! come hither, my trusty leech!
And bring me the Pills of Power.

And tell me, as thou art learned clerk
And I am a Baron true,
What mystic potion or secret art
To still my pains may do.

Oh, I am a wight of mickle might,
And skilled in Gramarye;
And the living I've blest, and I've cut up the dead,
In parts beyond the sea.

And I have learned, from ancient bokes,
And the Prince of the Powers of the Air,
The spells that wait on the Mighty Pill,
No mortal bowels may bear.

Oh, is it my liver has played me false?
Or are my lungs untrue?
Or has too much Old Ale made my stomach fail?
As Ale too much will do?

Oh, leave your liver and lungs alone,
And let your stomach be.
I can't explain to unlearned folks,
So leave all that to me.

The Baron he put out his long, long tongue,
The Doctor shook his head.
In nomine omium viscerum!
I conjure thee, go to bed!

The Baron he put in his long, long tongue,
And a fearsome vow swore he.
I'll see thee hanged on a gallows first,
With all the Facultie!

The doctor took, from a secret nook,
His pencil, good at need,
And he darkly wrote, on the back of a note,
What mortal may not read.

This mystic scroll will make thee whole,
If used at the mystic hour;
In the name of Jalap and Castor-Oil,
And eke the Pills of Powers!

REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 10, 1880.

Cities.	Population estimated for July, 1879.	Reported Deaths in each.	Deaths under Five Years.	Percentage of total Deaths from

Two thousand two hundred and eighty-three deaths were reported; 812 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 409, consumption 321, lung diseases 305, diphtheria and croup 175, scarlet fever 74, typhoid fever 34, diarrhoeal diseases 30, measles 28, whooping-cough 27, malarial fevers 15, erysipelas 14, cerebro-spinal meningitis 10, small-pox two (In addition, District of

Columbia reports 18 deaths from lung diseases, consumption 16, small-pox three, diphtheria and croup, typhoid fever, and diarrhoeal diseases two each, whooping-cough one,—total deaths not given.) In the cities, excluding District of Columbia, from measles, New York 20, Chicago six, Philadelphia and Brooklyn one. From whooping-cough, Boston seven, New York six, Philadelphia, New Orleans, Pittsburgh, Charleston, and Cambridge two, St. Louis, Cincinnati, Cleveland, and New Bedford one

From malarial fevers, New York five, New Orleans four, St. Louis three, Brooklyn, Baltimore, and New Haven one. From erysipelas, New York four, Brooklyn three, Philadelphia two, St. Louis, New Orleans, Cleveland, Worcester, and Salem one. From cerebro-spinal meningitis, New York, Philadelphia, Chicago, and St. Louis two, Pittsburgh and Worcester one. From small-pox, Philadelphia and Worcester one.

The total number of deaths reported is a little less than for the previous week,—of children under five four per cent. greater; consumption, typhoid fever, diphtheria, and small-pox were considerably less fatal; whooping-cough, malarial fevers, and measles caused more deaths; scarlet fever and lung diseases remained about the same. In 33 cities and towns of Massachusetts, with an estimated population of 380,910, the death-rate was 20.65; there was an increased mortality from scarlet fever, diphtheria, whooping-cough, and lung diseases; decreased from typhoid fever.

For the week ending December 20th, in 147 German cities and towns, with an estimated population of 7,615,550, the death-rate was 26.5 against 26.3 of the previous week. Three thousand eight hundred and eighty-one deaths were reported; acute diseases of the respiratory organs 510, pulmonary consumption 492, diphtheria and croup 200, diarrhoeal diseases 172, measles 97, scarlet fever 79, whooping-cough 65, typhoid fever 46, puerperal fever 26, varioloid (Berlin) one. The death-rates ranged from 10.8 in Libeck to 38.7 in Augsburg and Essen; Dantzig 30.1; Königsberg 29.4; Breslau 24.8; Munich 27.1; Dresden 21.0; Cassel 19.3; Berlin 24.0; Leipzig 31.4; Hamburg 29.1; Hanover 22.0; Bremen 22.6; Cologne 26.4; Frankfurt 19.8. Also Vienna 28.2; Prague 37.6; Paris 34.1. In 49 Belgian cities and towns, with an estimated population of 1,476,090, there were 946 deaths reported: bronchitis and pneumonia 215, pulmonary consumption 99, diarrhoeal diseases 46, small-pox (in

three towns) 33, typhoid fever 18, measles 13, whooping-cough 12, croup nine, scarlet fever four, diphtheria one. The death-rates were: Brussels 30.4; Antwerp 36.5; Ghent 33.9; Liege 37.4; 23 large towns 29.7; 22 smaller towns 34.5. Lung diseases, scarlet fever, diphtheria, and measles continued prevalent in Holland. The order of fatality of the prominent acute diseases in France continued to be lung diseases, diarrhoea, typhoid fever, small-pox (chiefly in Paris and Marseilles, slightly in Nice), diphtheria, and measles. In six cities of Austria, lung diseases, diphtheria, diarrhoeal diseases, small-pox (Vienna, Prague, and Trieste), measles, and scarlet fever were most prevalent. Typhoid fever is very rife in St. Petersburg, Milan, and Bologna.

For the week ending December 27th, in the 20 English cities with an estimated population of 7,383,999, the death-rate was 27.4 against 30.5 and 30.6 of the previous two weeks. Three thousand eight hundred and seventy-seven deaths were reported: diseases of the respiratory organs 652, whooping-cough 181, measles 160, scarlet fever 153, fever 37, diarrhoea 21, diphtheria 20, small-pox (London) two. Scarlet fever, lung diseases, and measles were declining; whooping-cough was especially fatal in London and Liverpool. The death-rates ranged from 16.8 in Brighton to 46.3 in Plymouth; London 27.1; Bristol 30.3; Birmingham 25.0; Liverpool 35.6; Manchester 28.7; in Edinburgh 21, Glasgow 27, Dublin 45. In the 20 chief towns in Switzerland, population 445,790, there were 49 deaths from acute diseases of the respiratory organs, diarrhoea 11, diphtheria eight, typhoid fever four, small-pox, scarlet fever, measles, whooping-cough, and erysipelas each one. The total death-rate was 28.0; Geneva 18.7; Zurich 29.8; Basle 31.0; Berne 44.9.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JANUARY 10, 1880, TO JANUARY 16, 1880.

TAYLOR, B. D., first lieutenant and assistant surgeon. Assigned to temporary duty at Governor's Island, New York harbor. S. O. 7, Department of the East, January 12, 1880.

CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE WEEK ENDING JANUARY 17, 1880.

ASSISTANT SURGEON W. G. G. WILSON to the Naval Hospital, New York, as the relief of Assistant Surgeon M. H. Crawford, detached and waiting orders.

Assistant Surgeon N. H. DRAKE to the Naval Hospital, New York.

Passed Assistant Surgeon D. O. LEWIS detached from the receiving ship Independence, and ordered to the Jamestown, at Alaska.

Passed Assistant Surgeon F. H. TERRILL ordered to the receiving ship Independence, Mare Island, Cal.

BOOKS AND PAMPHLETS RECEIVED.—Atlas of Histology. By E. Klein, M. D., F. R. S., and E. Noble Smith, L. R. C. P., M. R. C. S. Part IX. Philadelphia: J. B. Lippincott & Co. London: Smith, Elder & Co. 1879. (From A. Williams & Co.)

A Manual of the Practice of Surgery. By W. Fairlie Clarke, M. D. (Oxon.), F. R. C. S. Third edition, revised, enlarged, and illustrated by 190 engravings on wood. New York: G. P. Putnam's Sons. 1880.

Minor Gynecological Operations and Appliances for the Use of Students. By J. Halliday Groom, M. B., M. R. C. P. E., F. R. C. S. E. Edinburgh: E. and S. Livingstone, 57 South Bridge. 1879.

The Structure and other Characteristics of Colored Blood Corpuscles. By Louis Elsberg. Printed in the Annals of the New York Academy of Sciences, vol. I, Nos. 9 and 10. New York: G. P. Putnam's Sons. 1879.

A Manual of the Practice of Surgery. By W. Fairlie Clarke, M. A. and M. B. (Oxon.), F. R. C. S. From the last London Edition. Revised and edited, with additions, by an American Surgeon. New York: William Wood & Co. 1879.

Transactions of the New Hampshire Medical Society. 1879. The Alienist and Neurologist. A Quarterly Journal of Scientific, Clinical, and Forensic Neurology. Edited by C. H. Hughes, M. D., and an Associate Corps of Collaborators. Vol. I. No. 1. St. Louis, January, 1880.

Annals of the Anatomical and Surgical Society. Monthly. Edited by Charles Jewett, M. D. New York: G. P. Putnam's Sons. Vol. II. No. 2. January, 1880.

Quarterly Report of Medical Officers, United States Army, with their Stations and Duties. January 1, 1880. Washington: Surgeon-General's Office.

THE JOHNS HOPKINS UNIVERSITY AND HIGHER EDUCATION, WITH A GLANCE AT THE HOSPITAL BUILDINGS.

BY GEORGE HALSTED ROYLAND, A. M., M. D.

HIPPOCRATES complained of affairs, educational and professional, at Athens. A few centuries later, in the Augustan era, distinguished alike for its science, art, and literature, it was the custom to praise the past at the expense of the present. In the nineteenth century civilization and culture have attained such a high standard that the reverse is the case, and the present is praised at the expense of the past; at least, it is so with the authors of certain pamphlets and articles that within the past year or two have made their appearance in our current literature.¹ These productions, whilst deploring the low status of the medical profession in particular, and the mismanagement of American universities, medical colleges, and institutions of learning in general, impress strenuously upon the public mind the glaring necessity for a more elevated *esprit de corps*, with greater scientific attainments among practicing physicians and professors, together with the urgent need of a higher standard of education in every department. These deprecators hold, in some instances, diplomas of the very institutions they cry down, and are among the first, when perplexed, to call in consultation the more aged and experienced members of a profession whose status at other times only merits their contumely. The strifes and jealousies of rival schools are brought to light and dwelt upon.

And now, amidst all this educational anarchy, appears the Johns Hopkins University, with its brilliant array of talented professors and tutors (embracing some foreigners), to rescue our institutions, both general and special, from the total wreck that threatens their systems. Just as the Renaissance of arts and letters was commenced by the savants and artists of Byzantium, who, after the capture of Constantinople by Mahomet II., emigrated to France and Italy, and really did for them then what was later ascribed to the munificence of the De Medicis and François Premier. Such is the picture drawn of affairs, professional and educational, in their relation to the Johns Hopkins University, a production varying in ability according to the talent of the artist, but not true to nature, as will presently be demonstrated. Ten years ago the standard of educational requirements had made great advances as compared with the preceding decade, and from then up to the time of founding the Johns

Hopkins University it had been raised higher and higher, until the utmost was required of students, until examinations became more frequent and more stringent, and until admission examinations were instituted in our medical schools. In a word, during the last twenty years the rise and progress in medical, scientific, and academical education has been so gradual, yet so steady and so sure, that our present fault-finders, not perceiving it, have alone remained behind, ignoring the fact that we had, when the Johns Hopkins University was founded, a system of training in our universities, schools, colleges, and academies comparing favorably with those in any part of the world. This university of the future begins, then, where the others end, and comes to us as the natural outgrowth of advanced civilization and education, as the child of the elder ones, not inventing any new or patent method of intellectual schooling, but taking what is best from this one and that one, and what is deemed best adapted to the requirements of higher education.

The medical department, though not yet fully organized, will, it is understood, be represented to some extent by physicians and surgeons from our own city, and Baltimore can pride herself on having the varied talent, the many distinguished men, as well as the learned and ethical general profession belonging to a great medical centre, in which original research is encouraged, and the science and art of medicine are improved.

It was ascertained that much of the regular four years' college course could be omitted, especially by those intending to follow scientific or medical pursuits; consequently seven very concise courses of three years each are open to students as regular collegiate courses, which thus allow them to enter upon the university course, whether it be law, medicine, or theology, one year sooner. These seven courses are varied to meet the wants of all, and such branches are taught in them as bear directly upon the student's course in the future. Much stress is laid upon modern languages throughout, also upon philosophy and chemistry during these three years, whilst the introduction of biology into the preparatory medical course is an entirely new feature. It is well known that this is almost the last branch taught in foreign universities, but a study that requires such particularization may be useful as a disciplinary agent at first, not forgetting that an acquaintance with morphology should form an important part of a course preparatory to the final study of medicine; moreover, the mind of the student will have been sufficiently trained by his schooling in chemistry and physics during the first year to grapple with a subject that hitherto has erroneously been thought worthy of introduction only near the end of a five or seven years' university course. At the close of the third and last year of this preparatory course, which includes also German, English literature, history, and psychology, it is proposed to confer upon the successful candidate the degree of M. B., and thus give to this diploma a value in America. Although the recipient will not rank as does the English "medical man" who may practice upon it, yet it will be an advance in our educational gradations, and the American interpretation of the initials M. B. will probably be the more correct of the two. The biological course, which cannot be overestimated, will be one of wide scope, embracing the laws of life in general, whether exhibited in animals or plants; it is designed at the same time to give students at least a didactic knowledge of human anatomy and physiology;

¹ In the following article the author has made free use of the programmes of the Johns Hopkins University and of the Fourth Annual Report, edited by President Gilman, in order to show from them directly the relation of the new university to other institutions of learning, especially to the medical schools and the medical profession of Baltimore. The discussion on this point is just now going on with considerable vigor. The most striking article that has yet appeared is a pamphlet by John S. Lynch, M. D. This gentleman, for years a practitioner and professor of medicine in one of our leading colleges, ably handles his subject, and depicts the true condition of educational and professional affairs in our city. He has "seen none of the evils" denounced and deplored, but has noted many improvements and advances; among them are the establishment of several hospitals for the treatment of special diseases, the establishment of an out-door clinic at which more than thirty thousand patients are treated annually, courses with the use of the laryngoscope and microscope, etc. The increased number of professors in our medical schools, the high standard of the profession and their many and valuable contributions to literature, as well as their thriving societies, will give the gist of Dr. Lynch's article, which is heartily indorsed by all with whom the writer has spoken.

comparative anatomy and botany will not be required, as their general principles and more important facts are taught in the course of general biology. It will thus be seen that the student after such a course will be well advanced in his professional studies, and that the science of medicine proper will present to him fewer difficulties. It is of course understood that work in the physical and chemical laboratories forms a prominent feature in the schedule.

With respect to medical instruction in connection with the Johns Hopkins Hospital, the plan has not yet been definitely agreed upon by the trustees, but we may be sure that whatever system is determined upon will not be in imitation of any one routine, but will comprise what is best from the best. That this has been a ruling principle in the university organization throughout, the following lines from the Fourth Annual Report of the Johns Hopkins University, by the president, will attest. After referring to the extension of its influence beyond provincial limits, he says, "Having these aims, the next question to be considered was the interior organization of the university: Should it follow an American, an English, a French, or a German model; or should it gather from many sources educational methods to be adapted to the wants of this country, and brought into harmony with our conditions, political, ecclesiastical, and social? There was no hesitation on this point. The new foundation was to base its operations upon the experience of many and diverse institutions, ascertained by inquiries at home and abroad, among the most enlightened teachers and administrators."

Little has been said of scientific apparatus in this connection, but when we state that \$27,761 have been expended in that direction it will be readily understood that such appliances have been purchased of the best European and American makers, with especial reference to researches in regard to electricity, magnetism, and heat.

Another advance in higher education is the system of fellowships for the purpose of affording to young men of talent, from any place, an opportunity to continue their studies in the Johns Hopkins University, while looking forward to positions as professors, teachers, and investigators, or to other literary and scientific vocations. These Fellows are appointed by the trustees, and submit to examination; a small stipend is granted to them.

The new university has been favorably received by the medical profession of Baltimore, many of whom countenance the lectures and patronize the scientific courses.

Almost any day practitioners may be seen in the laboratories, and the library has become a sort of Pierian Spring (new books are kept on a stand and sold at a reduced price after three months), but no more so than the rest of the university, from which those who do not intend to "drink deep" are expected to withdraw. The Johns Hopkins University, recognizing the great benefit to be derived from a literature such as exists in other institutions of the kind, has given out the first volume of the *American Journal of Mathematics*, four numbers being promised annually; also the *American Journal of Chemistry*, six numbers annually. The writings from the biological department have been communicated to the *Journal of Physiology*, published in London and Cambridge. The influence of the university will doubtless be extended to a certain degree by the Fel-

lows, some of whom have been and others of whom will be called to different posts in this country, and by the scientific publications sent abroad. Nevertheless, it is more than likely that its usefulness and reputation will be principally local. Significant is the note that of the ninety-one collegiate students enrolled during the past three years almost all come from Baltimore and vicinity. All legitimate means will be employed to gain renown.

But fellowships are not altogether new; neither are university organs. This fact is mentioned in sustaining our claim that the higher standard attained is one that has been raised by the older universities, colleges, academies, and institutions of learning in general, not forgetting the much-abused medical schools, which certainly have contributed their full share in the onward march. The Johns Hopkins University, then, so far from being a deliverer from educational ruin, merely borrows what is best from all our institutions, merely comes under the standard already unfurled by them.

Before closing, let us leave the university proper, and take a casual survey of the hospital buildings, situated on an elevated piece of land something more than a mile distant. Seen from a distance, this collection of buildings forms an imposing memorial pile, more to the purpose than a sarcophagus of porphyry. For a description of the plan of these buildings the reader is referred to an article on this subject by the writer, and published in the *JOURNAL*, November 7, 1878. It is his intention at present to make a brief survey of the buildings themselves as they are now. The lot on which they are being built is fourteen and a half acres square, and when completed they will be twenty-five in number and in the form of a parallelogram. The main building, being the front, is on Broadway, but only the foundation, which is of brown stone, is laid. The height will be two hundred feet from the marble flooring to the lantern. On the right and left, and distant some sixty feet from it, are the male and female paying wards, each forming a separate building. These wards are arranged in such a manner that all the rooms open on corridors leading to the centre of the building, where is a skylight considerably over one hundred feet high. There are several floors of rooms. The next building in order, going to the left, is the kitchen, the first floor being divided into butcher's-rooms, store-rooms, pastry-rooms, etc.; but the kitchen proper is on the second floor, and is thirty feet by seventy. From this building all the meals will be furnished by means of a car, with hot-water chamber and on india-rubber wheels, pushed from building to building in the long and lofty connecting corridor. This corridor will be of artistic design, and will have a walk on top. Next in order comes the octagon building, so called from its shape. In the middle of this ward is the octagonal shaft to conduct off foul air. The beds will be arranged around this, feet to the shaft, the walls of which will be neatly finished and ornamented with works of art. It is thought that this will rest the weary eye of the patient, as well as break the view in such a manner that the sufferings of other patients will be in a great measure hidden, and their cries and groans during bedside operations more or less deadened. This ward is to be something of an experiment, and the idea has already been carried out in the Massachusetts General Hospital, the only difference being that the square is used there instead of the octagon. At the other end of this ward are small rooms for various pur-

poses, such as sitting-rooms and the like. Then come, at a distance of sixty feet, and at the same distance from each other, three charity wards; the only difference between them and the octagon ward is that they are parallelograms in form. Crossing the lot, the nurses' home is reached, a large, square building,—from the basement to the top seven stories high. The lower floors are devoted to dining-rooms, parlors, library, lecture-room, etc., and the upper ones to bed-rooms. There are, then, eleven buildings in process of construction,—eight actually under roof. It goes almost without saying that they are built in the best and strongest manner, with modern improvements, double ventilators, etc. Inside, the staircases are supported by iron pillars, and all the beams and girders are of the same material. The flooring and partitions are of lime, an imported French product, to which sand and cinders are added here. It is put up in large blocks, and the partitions in their present unfinished state resemble stone walls. The tiles, of the same material, for the ceiling and flooring are made so as to fit together between the iron beams and form an arch in themselves, leaving the ceiling and floor perfectly level. The buildings are all of brick, with black pointings, slate roofs, pinnacles, cupolas, and towers. The style selected is the so-called Queen Anne style, and the plan chosen seems to be a mixture of those of the Imperial Hospital of Leipzig, and St. Thomas's Hospital of London. It is hardly necessary to draw attention to the fact that for the exterior arrangements also the Johns Hopkins University is indebted to architectural designs already existing, both at home and abroad.

The surgical wards, waiting rooms, and clinic will form a separate department, and it is suggested to form eventually a school of surgery. The graduates would then receive some such degree as Bachelor of Surgery, Master of Surgery, or Licentiate. If such a diploma should not confer the right to practice, that right could easily be obtained from the Medical and Chirurgical Faculty of Maryland. The domain of gynecology will probably be included in that of medicine.

As to the length of the medical and surgical courses, the American system of three years is for our country and our needs decidedly the best, and is the one most likely to be adopted by the Johns Hopkins University. That graduates who have studied but three years have a less variety of scientific knowledge than those who have studied five years at a German university, or seven at a French one, other things being equal, is self-evident. But after graduation, in either case, a decade will, as a rule, elapse before the graduate gets into regular practice. During this period, by occasional cases, by reading, and by hospital study, the American will learn much. And it is fair to assume that the Frenchman or German, with his brain more or less overloaded, as he comes fresh from his laureate, will in these ten years have forgotten much in the way of botany, mineralogy, comparative anatomy, zoology, and even physics (which branches, except the last named, Huxley says ought to be rigorously excluded); so that time, the great leveler, will put them all on even footing when the hour arrives to enter into the active duties of brisk practice.

Without doubt, the critic will say, there is a certain similarity between the Johns Hopkins University and other existing institutions, just as in writing we sometimes speak unconsciously the thoughts of others. How could it be otherwise? True, but enough has

been adduced to prove conclusively the conditions under which the new university comes into being. That it may be grand and great cannot perhaps be denied; that it is original cannot be pretended; that it will be a success as a flourishing university, with crowded lecture-rooms, the future alone will show. In its struggles for existence it will be armed with wealth and intellect sufficient to place it on a par with, but not above, other American universities and medical schools. The Johns Hopkins University will owe its existence and status directly to an immense fortune that has been in possession of the trustees since the testator's death. But from the realm of departed spirits come back to-day the weird strains of the lyre. Listen: the immortal bard no longer sings alone his "Exegi monumentum ære perennius." It will¹ owe its intellectual standard to those very American universities, colleges, medical schools, and institutions of learning generally which from personal and selfish motives, too apparent to need further mention, have been ridiculed, as well as to the scientific attainments of the learned professions, especially that of medicine, which has been most unjustly sneered at by a minority so small as to be barely of sufficient consequence to remind that they owe everything to the very men they have sought to undervalue. Let the older institutions of education, then, welcome the Johns Hopkins University; let them take by the hand the child of their adoption, and invite her to march with them in the way of civilization and culture, to walk with them in the paths of knowledge, and to unite with them in the search for truth.

"That which hath been is now; and that which is to be hath already been, and God requireth that which is past."

MECHANICAL COMPRESSION IN ORCHITIS.

BY OCTAVIUS A. WHITE, M. D., NEW YORK.

WHATEVER is imperfect about the resources of art cannot remain, but must give place to every recognized improvement until perfection is attained. An inventor may zealously urge the importance of a cherished *eureka*, but the true value of the invention remains to be finally decided upon by a majority of those to whom its use is commended. In introducing, therefore, a novel treatment, a few preliminary remarks are necessary, setting forth what means to meet requirements are already at hand, what exigencies exist for something better, and, lastly, whether or not any one of these sufficiently fulfills the prime indications in view.

In the management of all affections of the male genital organs, acute or chronic, common or specific, idiopathic or traumatic, primary or secondary, necessity continually arises for the application of some form of mechanical support, combined with systematic and persistent pressure around the morbidly distended and

¹ The future tense is used because it will be three or four years yet before the hospital can be utilized for the reception of patients, and then a beginning will be made with only fifteen buildings. It is designed to receive four hundred patients. The space in the middle of the lot will be devoted to grass-plots, flower-beds, walks, benches for convalescents, etc., after the manner of many of our hospitals. We have already several large and well-appointed ones here, and with the new one the supply might perhaps exceed the demand. The floral display is evidently intended to be very fine, as in addition to the plots already mentioned there will be a green house one hundred and fifty feet long on the hospital grounds. What the precise object of this is I am unable at the present time to state; being left in the dark as to whether the flowers will adorn the beds of sickness exclusively, or whether anything in the way of renown or pecuniary gain is also expected from a source which, though it may be æsthetic, can hardly be considered very lucrative.

suffering contents of the scrotum. Past experience has amply proved that compression, timely adopted and judiciously regulated, to which rapidly disperses swelling and induration, to which these glands are prone, but absolutely preserves their delicate stroma from ruinous inflammatory changes liable to occur during a period of protracted intumescence. Nor is this recourse of value alone to effect resolution of swelling during the various stages of active engorgement. Orchitis is far more commonly a consecutive than a primary affection, and the result of repeated trial has shown that hereditary involvement of the testes, from propagated inflammation along the deferent duct or from the prostate gland, can possibly be averted by an early resort to this positive procedure. Even when the epididymis is attacked by primary disease, which is rare, or the urethra has been specifically assailed, moderate compression with support about the pendulous scrotum has always proved an effectual prophylactic against extension of the disease, and a measure of certain relief to the suffering patient.

Mechanical compression around the testes when in a state of disease requires no clamping at the present day to impress its importance. Attention to its expediency was no sooner directed by Fricke, of Germany, than the surgeons promptly recognized its value, and by the force of popular teaching this practice became permanently established wherever enlightened surgery is cultivated. So well established, indeed, is this mode of treatment that professional incapacity or culpable neglect may well be imputed whenever, in the management of affections of the testes, this salutary means of relief has been omitted. I further assert that when compression, with support, fails to improve the condition of an engorged testicle, the mode must be blamed, never the measure employed.

The act, however, of adjusting the imbricated dressing of Fricke to a diseased testicle is most commonly attended by great irritation and suffering on the part of the patient, and aggravated vexation and perplexity on that of the surgeon. All familiar with this method, so long in vogue, are well aware that the dressing, adjusted to day must, without fail, be removed to-morrow, and renewed with reinforced degree of compression, in order to follow up, *pari passu*, any advantage gained, as the swelling notably diminishes after each first application. When this process comes to be repeated every twenty-four hours for several successive days, the tender integuments are fretted, and often so intense is the degree of irritation that the surgeon is compelled to desist his treatment, thus affording the disease time and opportunity to rekindle into activity. It is necessary, moreover, that the adhesive-plaster dressing should be applied in narrow strips and successively. These must be laid on circularly, belting the tumor and overlapping each other, and the very best directed efforts have continually failed to subject every part alike of the tunicked organ to an equal degree of compression.

The theory of compression in respect to glandular swellings has been long in advance of its mode of application, and ingenuity has been kept exercised to invent some method of accomplishing the object in a manner at once convenient to the surgeon and painless to the patient. Among the various devices put forth at different times to meet this intention, none have thus far proved superior to the air-bag of Dr. Hutchinson.

surgeon to subject the parts *en masse* to such positive yet gentle compression as the exigency of each case demanded. But the bulk, weight, clumsiness, and liability to acquire and retain fetid odor so abundant about the region of the scrotum have always operated against its general use. Similar objections apply also to every other elastic or netted means intended to exert compression about the genitals for any length of time.

The announcement, therefore, of a new, safe, and painless method of instituting the desired amount of compression to effect resolution in engorged conditions of the testes should command favorable attention, not from sufferers alone, but also from surgeons, whose specialty induces a large share of genito-urinary cases to apply to them for relief.

The substitute which I have to propose, to carry out the above intention, will enable the surgeon to either moderate or intensify compression promptly and in accordance with his own sound views respecting the requirements in each particular case; and, while it never fails to accomplish the desired purpose with celerity and adequate firmness, the salutary aim is effected within the bounds of patience and toleration.

The instrument, as can be seen by reference to the subjoined wood cut, is shell-shaped, very light, and symmetrically molded to receive and accommodate within its cavity a swollen testicle, surrounded by its

scrotal integuments. The material of which it is composed is hardened rubber, special care being taken by the manufacturer to render the walls as thin and light as possible. About one third of the upper section of this shell is removed, leaving a preponderating portion of the base, which gives it the appearance of a scoop or dipper. The object of this configuration is of course apparent, and the peculiar shape selected has been found by experience to afford the very best mechanical support to the pendulous organ.

The cleft, which will be noticed, running down the front of the shield is intended to admit of free overlapping of the two thin edges. By this means ample provision is made for all necessary reinforcement of compression which is to be practiced during the management of a case.

In the fashioning of this splint special care has been taken to have that portion which is intended to surround the neck of the tumor smoothly everted, in order to insure against concentrated pressure, which might otherwise determine about the vessels of the cord when the shield is continuously worn.

The usual preliminary details to be observed in the act of applying compression to an enlarged testicle are

of course to be strictly observed. The patient must be placed in a recumbent posture sufficiently long to secure a certain amount of local depletion about the vessels of the part by gravitation. The affected testicle is separated from its sound fellow within the scrotum and fitted into a suitable-sized shield. At this juncture a narrow roll of bandage is cast around the upper part of the instrument, corresponding to the neck of the scrotal sac. This is to prevent the testicle from retreating upwards and outside the cavity in which it has just been placed. When this step of the process has been well effected, the surgeon has the testicle at his entire command, and can now subject it to any desired amount of compression by simply drawing upon the opposing lacing strings, which are immediately at hand.

Each shield is provided with a light elastic cord of sufficient length, by which the entire fixture can be suspended to the body with an ordinary figure-of-eight carried around the thigh and loins.

The mechanical difficulty of adjusting suitable compression to the pendulous scrotum will thus be found reduced to a very minimum by the very great simplicity of this device, and the apparatus, while inclosing the tender parts requiring treatment within its smooth and unyielding walls, safe from external violence and friction, can be habitually worn without personal inconvenience, and without attracting the least attention.

The rapidity, neatness, and comparative painlessness with which this fixture can be applied cannot fail to be favorably contrasted with the tedious, complicated, suffering, and uncleanly processes commonly employed, not one of which either surgical experience or mechanical skill can ever render more than tolerable. So rapidly, indeed, has reduction of swelling about these glands been effected by this means that it often becomes necessary, during its employment, to remove and readjust the shield twice instead of once in every twenty-four hours, — a convincing proof, surely, of its controlling power and comfortable accommodation.

Should at any time this appliance threaten to cause pain during the absence of the surgeon by inflammation gaining ground and giving rise to undue constriction, the dressing can be relaxed by the patient himself with promptness and ease.

It must be an exceptional case that will complain of pain either during or after the proper adjustment of this neat and gentle mode of applying compression to these glands; indeed, the patient is shortly relieved of all sense of aching, weight, and throbbing, which may have been primarily urgent, by the close adaptation of the dressing, and a degree of comfort is soon experienced not attained by any other means.

The prominent features of this scrotal shield, support, and compressor are remarkable lightness, the weight not exceeding eight grammes; great readiness and facility of application; consummate command afforded the surgeon over the degree and duration of direct pressure to the testicles, either singly or collectively; uniformity, firmness, and general diffusion of compression; entire painlessness attending and during its application or removal, even though the scrotal sac be well covered by hair; and, finally, perfect cleanliness, the fixture being so conveniently taken off and washed.

In cases of varicocele and inobscure sarcocele, upon which this instrument has been kept steadily applied, the relief has been speedy and highly satisfactory. Pending the necessary course of treatment in distress-

ing cases of neuralgia of the testes, I invariably employ it, and with most happy effect. When no other covering could possibly be borne upon the irritable organ, this has not only afforded protection and ease, but has enabled the patient to go about unrestrained in the open air, and attend to his ordinary avocations, 222 SECOND AVENUE, NEW YORK.

LITHOLAPAXY.

BY EDWARD T. CASWELL, A. M., M. D.

As every instance in which a new operation is successfully performed tends to establish still more strongly its claims upon the profession, I place this case on record. It affords one more proof that the procedure brought forward by Dr. Bigelow has been a contribution of positive value to surgical science. The case was reported in brief at the last meeting of the Rhode Island Medical Society.

J. L., aged seventy-one, had suffered for three or four months with pain referred to the penis, frequency and scalding in micturition, and stoppage of the stream. An examination showed the presence of a small calculus, and on November 10, 1879, four days after the examination, I proceeded to perform litholapaxy at the home of the patient, in the country.

I found the urethra capacious, being able to pass without difficulty No. 30 (French) of Van Buren's sounds. The prostate gland was considerably enlarged, the bladder sufficiently roomy. The first crushing was done with Bigelow's lithotrite, but subsequently, for the purpose of comparing the two instruments, I used Keyes's modified lithotrite. Bigelow's evacuating apparatus was also used, although it had not the modifications recently introduced.

I first attempted to pass the straight tube No. 30, but as I did not succeed it was withdrawn, and No. 29 curved was passed. Through this a few fragments were evacuated, but as it did not seem satisfactory I withdrew the tube and made another and successful attempt to introduce the straight one, No. 30. Quite an abundance of debris now passed, and I continued to use this tube, although with each introduction the same difficulty was experienced, and to this is to be ascribed a large part of the time consumed in the operation. The crushings and evacuations were repeated four or five times, and at last I failed to find any further evidence of stone with the searcher.

Many of the fragments were quite large. One, which was removed early in the operation, and which was by far the largest, measured five eighths by three eighths by two eighths of an inch, and weighed ten grains. It showed a nucleus perfectly imbedded in a complete portion of the shell. This piece was drawn into the eye of the tube in such a fortunate manner that it presented a perfectly smooth surface to the urethral walls, and was removed without inflicting the slightest injury upon the urethra. Another nucleus was found entire in the contents of the bottle, showing that there were two stones. The nucleus was pure uric acid, and the shell contained about two per cent. of phosphatic salts, the remainder being uric acid. The whole amount evacuated weighed, when dried, ninety-eight grains, and the time occupied in the operation was about two hours and a half. There may seem to be a great disproportion between the time employed and the amount

removed, but much of the time was spent in introducing the straight tube, and in making a final search. Something also was to be attributed to the fact that it was the first time I had performed the operation. I had the satisfaction of knowing that the bladder was thoroughly freed from stone; for although the water was passed through a strainer for several days, no fragments of sand passed after the first forty-eight hours, and in that time only a few small fragments weighing four grains.

Scarcely any blood was lost in the operation. The patient rallied from the ether, and complained of but little pain. In seven days from the operation he walked out, and was "feeling better than he had for months." Up to this date he has not had the first sign of any return of his former trouble, has resumed his vocation, and considers himself perfectly well.

PROVIDENCE, R. I., January 10, 1880.

RECENT PROGRESS IN FORENSIC MEDICINE.

BY F. W. DRAPER, M. D.

Sub-Epicranial Ecchymosis and Cephalhematoma.—According to M. Charles Féré,¹ these two lesions, so common in new-born children, and so important from a medico-legal point of view, are to be carefully distinguished the one from the other. Sub-epicranial ecchymosis is oftenest seen on the parietals, along the sagittal suture; but instead of being, as is the case with the cephalhematoma, limited to a small region, it can extend so as to include the greater part of this bone, and it may even be found in other regions of the cranium, as the frontal and occipital. When this lesion is examined on the dead body of a new-born infant, the pericranium is found in great part detached, and its union to the subjacent bone is by a few isolated points only; it is raised by a layer of blood, which is more or less liquid, according to the age of the effusion. If, however, one has to do with such an ecchymosis in the reparatory stage, one finds the periosteum no longer separated from the bone by a layer of blood, but firmly adherent to the bony surface; the bone itself, when stripped, presenting a dark red color. In cephalhematoma, in the stage of repair, section of the bone presents superficially, under the pericranium, an ossiform layer which covers the bloody effusion, and underneath, the bone itself appears porous.

The anatomical characters of these two lesions, macroscopic as well as microscopic, show very well the differences in their manner of production and of repair. It is always a subperiosteal hemorrhage; but in cephalhematoma the effusion which is made by the rupture of a relatively large vessel is sufficiently abundant to raise the periosteum completely; while in ecchymosis the effusion caused by the laceration of many small vessels is not sufficient to detach all the adhesions of the pericranium and to form a distinct tumor.

A Case of Rapid Post-Mortem Emphysema.—Dr. William G. Porter has presented a case² which has a medico-legal interest in its relation to the question of decomposition as a means of determining the time of the death in any given case. The patient was an Englishman, fifty-eight years old, of stout build, of temperate

habits, though a large eater; he was a healthy man, so far as was known, until his last illness attacked him. Dr. Porter was called at five A. M., October 4th, to prescribe for the relief of excruciating epigastric pain which had supervened after several days of nausea, with occasional vomiting. Morphia, given hypodermically, controlled the pain; and other measures were adopted to palliate the attack and to prevent its recurrence. Moderate fever developed, and in the course of the day several large, soft, bilious stools were passed. At midnight there was more pain, still referred to the epigastrium; the skin was warm, but the patient was pulseless at the wrist; full collapse developed presently, and death ensued at about one A. M., October 5th. An undertaker was immediately summoned, and the body was placed in ice within two hours after death. At eight o'clock in the morning the body had swollen "enormously;" at nine the corpse by its distention had lifted the lid of the ice box several inches, carrying with it a layer of ice that covered it. The whole surface of the body was jaundiced. The features were distended beyond recognition, and the face was smeared with clotted blood which had been forced from the bloated mouth and nostrils.

When at this time (eight hours after death) the usual post-mortem incision was made in the median line of the body, air without appreciable odor escaped from the cellular tissue; the tissues receded from the knife as if they had been stretched to the utmost. A large amount of air, also without odor, escaped from the peritoneal cavity, although there was no peritonitis. The liver, kidneys, and spleen were emphysematous and buoyant. The heart was empty, and its tissue was friable. There was no odor of putrefaction.

Cremation in its Medico-Legal Aspects.—This subject has received the attention of the Société de Médecine légale de France, a full and interesting discussion having ensued on the presentation of an essay on the topic by M. Ladreit de Lacharrière.³ The sanitary relations of the theme received ample consideration also, but with these we are not now concerned.

M. Lacharrière took the ground that, from a medico-legal point of view, cremation is open to the gravest objections. Before any dead body is submitted to incineration, there should be, he says, certainty upon two points: the fact of the death itself and the cause of the death. Verification of the death is not difficult, especially in cities which can adopt the Parisian system. But accuracy as to the cause of the death is not an easy matter to manage; medical certificates do not solve the question, nor is the ordinary autopsy, performed, as it is, without any presumption or suspicion such as forms the basis of a medico-legal examination, a sufficient safeguard against crime. Therefore it would be unsafe to proceed, upon such inadequate means of detecting in the body the true cause of death, to destroy the body by cremation, and thus throw away the opportunity for reinvestigation. Finally, M. Lacharrière supposes two instances, either one of which is likely to occur: A person dies, presumably of heart disease, but really by a poisonous dose of digitalis administered with criminal intent. The autopsy establishes the presence of heart disease, and the crematory furnace is allowed to do its work, whereby the real evidence of the crime is destroyed, and the criminal escapes. Or, in the second case supposed, no crime

¹ Bull. Soc. anat., 1878, page 160; Le Progrès méd., 1879, page 424.

² Traus. Coll. Phys. of Phila., Third Series, vol. iv., page 79, 1879.

³ Annales d'Hygiène publique et de Médecine légale, June and July, 1879.

has been committed, but popular gossip accuses unjustly one of the relatives of the deceased. What proof will the accused be able to furnish, after cremation of the body, that he is really innocent?

Thus, by enabling the traces of a crime to disappear, cremation leaves society defenseless; it can likewise make it impossible for an innocent man to answer baseless calumny.

In the discussion which followed the reading of this paper, M. Napias expressed the opinion that cremation offered no real obstacle to the detection of crime in cases of death by violence, and that burial had no special advantages in this regard. If a death has been the result of mechanical violence, the case presents no difficulty, since the injuries could hardly escape observation. In cases of poisoning, however, there would be more difficulty. In this connection, M. Napias would divide poisons into two classes: those which could not be recovered from the ashes of a cremated body, such as organic substances, mercury (because of its volatility) and phosphorus (normally present in the body); and, secondly, those which can be traced after incineration, such as arsenic, antimony, and copper. Poisons of the first class disappear in case of burial as well as in that of cremation; poisons of the second class are found just as readily in ashes as in the remains of buried bodies. Moreover, as a matter of fact, the majority of exhumations are made to determine the nature of mechanical injuries, not of toxic agents.

In cases of death occurring without an attending physician, M. Napias would not permit cremation, except after a complete autopsy; and if the slightest suspicion were entertained as to the manner of the death an inquest also should precede the final disposition of the body.

M. Gallard argued that the autopsy was an ample safeguard against any medico-legal misadventures of cremation. This will almost always reveal the cause of death, and should invariably be applied. In the exceptional cases where the cause of death is not thus determined, there should be in addition a chemical analysis, and possibly an inquest also. M. Gallard stated that he would subject to cremation all dead bodies not claimed by friends, such as those of executed criminals, of persons dying in hospitals or prisons, and those carried to the morgue and not identified.

M. Riant believed that cremation would expose society to the most serious dangers from a medico-legal point of view, because a crime frequently escapes suspicion till long after the death of the victim, and cremation renders impossible the demonstration of the crime and the punishment of the criminal. He did not think that the ordinary medical certificate of the cause of death, liable as it is to many errors, afforded much protection against the dark deeds of criminals. Cremation, after such a certificate, will have rendered a mistake irremediable and a crime unpunishable; burial, on the contrary, preserves for us the *corpus delicti*, and permits the condemnation of the guilty.

He pointed out the impracticability of M. Gallard's proposal to have an autopsy in every case before cremation; in Paris alone nine hundred autopsies would be required each week. The difficulties in the way of chemical analysis as a prerequisite of cremation would be even greater. In cases of poisoning, in which chemistry lends its aid under present methods, the

chemist has clues and presumptions, if not proofs, which he simply verifies; and even with these advantages much time and great care and delicacy are needed in the processes employed. The chemical search which M. Gallard would impose would be simply a search in the dark, without guide or hint as to the result; such an investigation could not be seriously undertaken.

To the suggestion of M. Napias that the organic and volatile poisons are the only ones liable to loss through cremation, M. Riant replied that these were in fact the poisons most commonly used by criminals, and for obvious reasons. Moreover, granting that the ashes resulting from cremation may be found to retain mineral poisons, it is easy to see how readily these ashes might be scattered or destroyed by the criminal, or other ashes, innocent of poison, substituted. M. Riant also reminded M. Napias that, while gross mechanical lesions would undoubtedly be seen and investigated, there were means and agents not unknown to criminals that would leave slight traces of their fatal work; there are wicked mortals who know that a needle or a pin is useful in infanticide, and that it leaves but scanty evidence of its use.

An inquest before cremation M. Riant deemed of little practical value, since the interval of thirty-six or forty-eight hours available in such a case, between the death and the furnace, is generally much too short for the manifestation of suspicions or pointed rumors, upon which alone an inquest would be well founded, or the machinery for the detection of the criminal set in motion.

M. Riant would reserve cremation for use in seasons of fatal epidemics and for the disposal of the bodies of soldiers after great battles.

Recovery after Severe Injury to the Brain.—The question sometimes arises in court, "Is not such a wound—one, for example, penetrating the brain, or the heart, or the lungs—necessarily fatal?" The first impulse would be to answer in the affirmative; yet a sufficient number of remarkable recoveries is on record to constitute a respectable minority of exceptions to the rule of fatality. The following case,¹ reported by Assistant Surgeon P. F. Harvey, U. S. A., will illustrate the necessity for the use of caution in giving testimony that a bullet wound through the brain is inevitably deadly.

The patient, an Indian-agency physician, received a Winchester-rifle ball three inches and a quarter above and one inch behind the right external auditory meatus. The missile took a transverse direction across both hemispheres toward the left supra-orbital convolution, a grooved director being easily passed in that course, a distance of five inches, without, however, reaching the ball. The patient did not lose consciousness on being wounded, and complained only of "seeing stars" and of some confusion of ideas; he recovered so rapidly that after thirty-five days of convalescence he took a journey of ninety miles, in December, in an open buggy, alighting several times to make his way on foot through deep snow-drifts. At the end of this exertion, however, two convulsions occurred, and the wound in the head reopened. Subsequently, various threatening symptoms supervened, but they were all happily managed, and complete convalescence ensued. Six months after the wounding the patient

¹ American Journal of the Medical Sciences, July, 1879, page 146.

traveled across the plains to his home in Indianapolis, and on his arrival reported himself in excellent condition.

In this connection may be mentioned an instructive paper by Dr. H. R. Wharton, of Philadelphia,¹ wherein he gives an analysis of three hundred and sixteen recorded cases in which foreign bodies were lodged in the brain. Of these 316 cases, 160 recovered and 156 died. There were 106 cases in which the intruding body was removed; the result in these instances was fatal in 34; of the 210 cases in which the foreign body was allowed to remain in the brain, 122 ended fatally in consequence, and 88 recovered. Brodie's opinion, that recovery is more apt to follow wounds of the anterior portion of the brain, is confirmed by an examination of the cases in the present series, where the foreign body penetrated the frontal bone: of these, 132 in number, 58 ended fatally and 74 resulted in recovery. The parietal bone was penetrated 58 times, with 27 deaths and 31 recoveries. The occipital bone received the lesion in 23 instances; 16 of the subjects died and 7 recovered. The foreign body entered the brain through the temporal bone 31 times; there were 12 deaths and 19 recoveries. Wounds of the orbit were by far the most fatal; there were 18 cases on record, all but one of which resulted fatally.

Recent Decisions.—The following are notes of decisions by the courts concerning matters of medico-legal interest:—

(1.) In the trial of a man indicted for rape,² the complainant testified that the defendant and some others seized her on the street at night and carried her into an alley-way, where he and the others ravished her. There was a verdict of guilty, and the defendant moved for a new trial. The defendant requested the court to charge the jury that, to constitute the crime of rape, it was necessary that the prosecutrix should have manifested the utmost reluctance, and should have made the utmost resistance. The court did not comply with this request, and the refusal to do so was made the ground for asking a new trial. The importance of resistance was held by the supreme court of appeals, before which the motion came, to show two elements in the crime: carnal knowledge by force by one of the parties and non-consent thereto by the other; and the jury must be satisfied of the existence of these two elements in every case, by the resistance of the complainant if she had the use of her faculties and physical powers at the time, and was not prevented by terror or the exhibition of brutal force. So far, resistance by the complainant is important and necessary; but to make the crime hinge on the uttermost exertion the woman were capable of making would be a reproach to the law as well as to common sense. Such a test it would be exceedingly difficult, if not impossible, to apply in a given case. If the failure to make extreme resistance was intentional, in order that the assailant might accomplish his purpose, it would show consent; but without such intent it shows nothing important whatever. A new trial was not granted.

(2.) A man murdered a woman by shooting her; his defense was that he was intoxicated, and thus irresponsible.³ The case came before the Nebraska supreme court on exceptions filed by the defendant.

The court reaffirmed the principle, now tolerably well established, that "settled insanity, produced by intoxication, affects the responsibility in the same way as insanity produced by any other cause; but insanity immediately produced by intoxication does not destroy responsibility when the patient when sane and responsible made himself voluntarily intoxicated."

In the same case, it was held that the fact that the prisoner was in a drunken state when he committed the homicide does not in itself render the act of shooting the deceased any the less criminal, nor is it available as an excuse.

(3.) A midwife volunteered to cure an attack of ophthalmia in the infant at whose birth she assisted, and whom she was nursing.⁴ She advised the parents that it was unnecessary to call in a physician, as she had successfully treated similar cases. The sight of the child was destroyed. The mother of the child brought an action to recover damages. At the trial there was medical evidence that if other and more active remedies had been used loss of sight would not have resulted. The midwife did not pretend to know of these remedies.

The case was carried from the superior to the supreme court on exceptions, the lower tribunal having dismissed the suit with a verdict for the midwife, without giving the case to the jury. The supreme court confirmed this disposition of the action, on the ground that a person who without special qualifications volunteers to attend the sick can at the most be required to exercise the skill and diligence usually bestowed by persons of like qualifications under like circumstances. Under the rule requiring ordinary care, as applied to this case, the court saw no evidence of neglect in any degree. [That is to say, the midwife showed no greater skill than she pretended to possess,—a safe harbor for incompetency.]

(4.) The liability of hospitals for the consequences of the acts of their visiting physicians and surgeons on duty has recently been tested anew in a case in New York,⁵ and the principle is reaffirmed that if such institutions have exercised due diligence in securing skillful and careful medical men to treat their patients, they cannot be held accountable for alleged malpractice on the part of these medical officers.

One of the surgeons of the Manhattan Eye and Ear Hospital, after consultation with both his colleagues, advised and performed an operation for chronic glaucoma. The necessity of an operation was agreed to by the three consultants, and there was no accident during its progress. Two weeks later the patient left the hospital with vision exactly the same as when she entered. In a few days after her discharge, inflammation developed, and she returned to the hospital for treatment. Another operation was advised, and the patient consented to its partial performance. The operation had no permanent beneficial effect, and the woman became blind. She brought a suit against the hospital for fifty thousand dollars for the loss of her sight. The trial took place before the New York supreme court, Judge Lawrence presiding. After a full hearing of the testimony, in which, on the part of the hospital, it was shown among other things that no complaint was made at the time of the alleged injury to the surgeons or to any of the hospital authorities

concerning the surgical treatment; that the surgeons were men of preëminent skill in their profession, and had pursued the usual methods of diagnosing and treating chronic glaucoma, — a disease which almost inevitably ends in blindness, — the judge dismissed the complaint, without giving the case to the jury. This decision in favor of the hospital rested on and reaffirmed the principles set forth in a judgment rendered by the supreme court of Massachusetts in a similar case,¹ the essential points being that the Manhattan Eye and Ear Hospital was a charitable institution which, having exercised due care in the selection of its agents, was not liable for any injuries to a patient caused by their negligence; that, in the present instance, there was no proof that there had been any negligence whatever on the part of the surgeons, who were shown to be men of superior skill, and to have exercised their skill with proper caution.

Hospital Practice and Clinical Memoranda.

CLINICAL LECTURE ON DISEASES OF WOMEN.

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

BY PROFESSOR T. GAILLARD THOMAS.

[Reported by P. Brynberg Porter, M. D.]

PROBABLE CARCINOMA OF THE OMENTUM.

GENTLEMEN: This patient was sent to me by Dr. Campbell, of this city. She is a native of Ireland, is forty-three years of age, and has had seven children, but no miscarriages. Her last child was born twelve years ago.

As the woman is very deaf, it will be necessary to get the history of the case from her daughter, who comes here with her. The latter tells me that her mother has been really ill for three months only, but that she suffered from dyspeptic symptoms for two years before that. Three months ago she began to feel such soreness about the abdomen that she consulted Dr. Campbell, and, on making an examination, he discovered a tumor in the situation where the pain was located. But laying the matter of the tumor aside for the present, let us inquire a little further concerning the symptoms from which the patient has suffered. On doing so, we find that she has wasted away in the most marked manner, and that she has lost so much strength that she cannot now go up-stairs without assistance. Besides, a great change in the color of the face has been noted, and she is to-day excessively pale and anæmic looking. Yet there has been no loss of blood whatever to account for this wasting of strength and cachectic appearance. What she complains of principally now, in addition to weakness, is great pain and soreness about the abdomen. There has never been any derangement of any kind of the menstrual function, so far as we are able to ascertain.

Now here is a woman approaching the menopause who was perfectly healthy up to two years ago. At that time, her daughter tells me, she lost her husband, and her general condition at once began to depreciate. The principal symptoms have been dyspepsia, loss of appetite, loss of flesh and strength, and marked pallor of countenance; and she has at length become so weak

that any exertion is burdensome. When we look at her face, we see at once that some grave trouble is present in her system. It is the face of an individual who might be suffering either from great loss of blood, or from a poison affecting the blood. In some maladies both causes combine to produce such an appearance of countenance. Thus, in Bright's disease there is, first, a loss of albumen, depriving the blood to a greater or less extent of its nutritive power, and, secondly, an actual poison present, which the kidneys do not eliminate, and which accumulates in the blood. Let us now proceed to make out, if possible, what the trouble really is here.

It has been stated that her physician found an abdominal tumor, and it is a matter of great importance that its character should at once be ascertained. When we examine it, we find that it consists of a round, firm mass, of considerable size, which is situated a little to the left and on a level with the upper edge of the umbilicus. Its surface is hard, resisting, and nodular, and feels actually *brittle* to the touch, if I may use the expression. Now, if this is an ovarian tumor, there is an excellent chance of a successful operation and the saving of the patient's life, and you can therefore see of how great consequence it is in such a case to arrive at the diagnosis as promptly as possible. Even if it is a solid tumor of the ovary, her life may be saved; as in the case of the patient who was before you in the early part of the course, and upon whom I afterwards operated at the Woman's Hospital. When she was leaving the hospital, a short time ago, she came up to say good-by to me, and she had actually grown so stout during the past two months that I did not recognize her at all. Yet the present patient looks quite as badly as she did when she first came to the college. The all-important question here, then, is, What is the diagnosis? This being determined, we ask, in the second place, What can we do for her?

After a careful examination of the case, I do not hesitate to say that my opinion is that no operation will ever be performed in this case. There is nothing about the tumor that points either to the uterus or the ovaries; and in the history, as you have heard, the patient has complained of no menstrual disorder of any kind whatever. There has been here simply a gradual failing of strength and health, a general giving way of the constitution. When an examination of the pelvis is made, nothing at all can be felt of the tumor, and there is well-marked resonance over a considerable space between the latter and the pelvis. The mass is entirely immovable; and I believe it to be of malignant character, in all probability connected with the omentum. It does not seem to belong to the intestines; because if this were the case, it would probably give rise to well-marked symptoms, such as tympanites, severe localized pain, and possibly dysenteric diarrhoea.

But you may ask, Why not cut down upon the tumor? In such cases as this the patients themselves are often very anxious to have an operation performed for their relief; but we are to remember that the true surgeon always acts for the good of his patient, and not merely for the advancement of medical science. Here I do not doubt that toxæmia already exists, and I firmly believe that no operative procedure whatever would be of the slightest service. All that we can do is to endeavor to keep up the strength of the patient, and render her as comfortable as possible.

¹ McDonald v. Mass. Gen. Hospital, 129th Mass. Rep., page 423.

POST-UTERINE FIBROID.

Elizabeth C., aged twenty-two years, and a native of the United States. She has been married four years, and has had two children, which were both still-born at full term. Her last confinement occurred five months ago, and she has never had any miscarriages. How long have you been complaining? "Since my first child was born." How have you suffered? "I had severe after-pains just after the birth of the child." How long did these continue? "They have never left me at all, scarcely." And yet you have had a second child since? "Yes." (This is certainly a very strange history.) Did you suffer the same pains while you were pregnant also? "Yes, all the time." Then did they continue after the birth of the second child, too? "Yes, and on up to the present time." How does this pain affect you? "I feel all the time as if I could force something out." And is the pain very bad? "Yes; oftentimes I cannot get any sleep either by night or day." Does the pain ever wake you up at night? "Yes, often." Do you ever have to bear down as if you were actually in labor? "Sometimes." Do you ever expel anything? "Yes, lumps of blood." When is this, — at the time of your monthly periods? "Yes, and between these, too, sometimes." When you are free from these pains you feel pretty well, do you not? "Yes, but I have a discharge all the time." How long have you had that? "Ever since the first child was born." Do you suffer much pain at the time of your monthly sickness? "Not very much." Do you feel easier then than at other times? "Yes, always." How long does your sickness usually last? "About five days."

Now I do not remember ever to have heard just such a history as this young woman has given us; and it naturally excites our curiosity to find out what may be the cause of the peculiar trouble experienced here. When we make an examination, however, everything is clear about the case, except the treatment.

But before giving you the results of the exploration which I made here, let me relate briefly a somewhat similar case, for the purpose of showing the necessity of resorting to a physical examination in every instance where the symptoms point towards trouble about the pelvic organs. Whoever fails to do this, or at least propose it to the patient, is very culpable. A short time ago a lady from out of town came to my office with the story that for the past eighteen months she had suffered such acute pain that her physician was obliged to almost narcotize her in consequence; so that he deemed it prudent to keep a galvanic battery in readiness, lest she should at any time get too fully under the influence of opium. Sometimes he would have to give her two or three hypodermic injections of morphia during the same night. The pain was principally noted in the right iliac fossa, but also extended further up the side and down the right lower extremity. During the eighteen months a number of consultations were held in regard to the case, but no examination was ever proposed. Let me say that the examination in this case is not likely to result in any good to the patient; but it will certainly prove of great service to her physician, because he will now know what the actual condition is, while before he was in total ignorance in regard to it. When I examined the patient, I found that the uterus, was pushed considerably over to the left side, and that a solid fibrous tumor to the right of it was pressing with such force upon the sacral nerves as they entered the

pelvis that no amount of force applied through the rectum could lift it off of them. I believe the mass is wholly immovable and irremediable; still it is well to know what the condition really is.

But to return to the present patient. The woman lying upon her back, I made a vaginal examination, and found the uterus about in normal position, with the exception that it was tilted just a little forward. Behind it, however, I soon ascertained that there is a mass about as large as a hen's egg attached to the organ in the position which I indicate upon the blackboard. This is also a fibroid; but, unlike the one of which I have just been speaking, it is not pressing upon the foramen and the sacral nerves, though it is seriously interfering with the innervation of the uterus.

You remember that the patient said that both her children were still-born, and on questioning her more particularly in regard to her labors I find that in the first one she was delivered with forceps. I do not doubt that the reason why the forceps had to be resorted to was the presence of this fibroid. It is now as large as a hen's egg; but you must not forget that such masses increase with the size of the uterus during gestation, so that at the time of the delivery it was no doubt at least two or three times as large as it is at present. Such tumors are of very much the same character as the mass of the uterus itself; so that Virchow thinks they should not be called fibroids at all, and has termed them myomata. In such a case as this there is a great accumulation of blood in the uterus, — a metro-stasis, as it is sometimes called. But the bearing-down sensation on the part of the patient is not due, you must understand, to blood in the uterine cavity.

Now as to the treatment. Any one who would attempt to remove this tumor by surgical interference, I hold, would be exceedingly culpable; because, as you can easily perceive at a glance, the patient is in excellent general health. Yet, in another case, where death itself may be imminent from the bad effects of the growth, the operation of removing it would be not only justifiable, but imperatively demanded. The surgeon who should hesitate to operate in such a case ought to be considered culpable for his cowardice or negligence. What I would suggest in this instance is the persistent hypodermic injection of ergot; and there is no preparation that I know of better for the purpose than Squibb's fluid extract. This should be resorted to two or three times a week; commencing with five drops, and gradually increasing the amount to fifteen drops. In this way I should hope to control the pain to some extent, at least. Ergot acts by causing the muscular coats of the arteries to contract, and I have known its administration to occasion marked diminution in the size and increase of the firmness of even the radial artery.

But you must remember that the nervous system is affected by such a condition as this; although whether a trouble of this kind will cause much disturbance or not must depend on the state of the patient at the time. In the same way, a woman may have cystitis for a long time, and yet scarcely be aware of its existence until she meets with some affliction or source of anxiety, when she will begin to suffer terribly from it.¹

¹ This patient having come under my care, I tried the experiment of giving ergot by the mouth before resorting to its use by hypodermic injection; and so beneficial did its effects prove in this case that I found it unnecessary to employ the latter. She was placed upon half-drachm doses of Squibb's fluid extract of ergot three times a day, and almost from the first the pain of which she had been com-

RETROVERSION EXISTING FOR A CONSIDERABLE TIME WITHOUT SYMPTOMS.

Our next patient is Margaret H., born in Ireland, and thirty-five years of age. She has been married thirteen years, and has had three children and one miscarriage. She was last pregnant two years ago, and that was the time when she had the abortion. When questioned as to her history, she states that she was well up to two months ago, when she lost a child five years of age, and was greatly overcome in consequence. Since then she says she has had a constant pain in the back and has grown very pale. That is all that she complains of. There is no difficulty whatever about her menstruation, and she has no leucorrhœa.

In connection with this case, also, let me relate another, occurring in my private practice. To-day a lady was sent to my office from a neighboring town who for some time has been under the care of two of the best physicians which I know of within forty miles of New York. Retroversion was supposed to exist, and so all sorts of pessaries were applied for its relief; but all without effect. The diagnosis was incorrect, however, simply because the examination resorted to was not made with sufficient care. When I investigated the case myself, I found that there was no retroversion at all, but, instead of that, an ovarian cyst of slow growth down in Douglass's cul-de-sac. Accordingly, I recommended that the cyst should be evacuated by means of the aspirator, the needle being passed through the posterior wall of the vagina. In case this should fail, I advised that vaginal ovariectomy should be performed.

In the present instance I thought at first that the same condition might exist; but when I felt for the body of the uterus in the usual position, it was wanting. Consequently, I at once changed my view of the case. In the other one, however, I could readily feel the body of the uterus; while below it was the mass described. The trouble in it was that the attending physicians were careless in their examination, and because they found something down in Douglass's cul-de-sac took it for granted that the uterus was retroverted. If they had explored the cavity of the organ with the probe, they would have ascertained that the fundus was in its proper position, and, consequently, that the mass that they felt below must be something else. When I introduced the probe in the case now before us (the patient's position being changed to the side), I found that there was very marked retroversion, the diagnosis being made positive in this way. In such cases the passage of the uterine probe is the *experimentum crucis*.

The question now arises, When did this retroversion occur? I have not the slightest doubt that it was caused two years ago, when her last child was born; and yet it has never given her any trouble at all until lately. You will find large numbers of strong, healthy women who go about perfectly well for a long while with marked retroflexion of the uterus. Then they meet with some trouble or worry, and from that time it renders them miserable. Here, as we have seen, the patient two months ago lost a child, over which she grieved a great deal; and ever since then she has suffered from pain in the back, and has been growing pale. This, you perceive, only goes to confirm the truth of placing so long altogether disappeared. The fibroid also diminished notably in size, and when the patient was last seen (after a prolonged course of the ergot) it was scarcely appreciable in an ordinary uterine examination. — P. B. P.

what I said, in connection with the last case, in reference to patients not infrequently being the subjects of serious disease, and yet suffering no bad effects from it until some trouble occurs which produces a depressing effect upon the nervous system.

The next question is, What is the prognosis? There are so many cases which come here in which I make the diagnosis for you, and then have to confess that little can be done for the patient, that I am always glad to meet one, as in the present instance, in which the prognosis is altogether favorable. All that is necessary here is to restore the uterus to its normal position, and then apply an appropriate pessary to retain it there. This restoration should be made by lifting up the fundus with two fingers if possible, and not by means of the sound or repositoir, if it can be avoided, as any instrument whatever is liable to do injury if carried up into the uterine cavity. In this way I believe the patient may be entirely cured, although she may have to wear the pessary for six months, or even a year.

The treatment here, you observe, is a mechanical affair altogether; and it would simply be a piece of folly to put in the pessary before the uterus has been restored to position, as is not infrequently done, even by those who ought to know better. It is such men as this whom you will hear declare that "pessaries are perfect humbugs." But not only can a cure not be effected by such a procedure, but an attack of pelvic peritonitis is very apt to be set up in consequence of it. As well might a surgeon, when called to treat a fracture (of the forearm, for instance), apply a splint, while he leaves the fragments of the bone overlapping each other. The design of splints in such cases is merely to maintain what it is necessary first to establish, *apposition*.

Is any other treatment called for in addition here? Not at all. When the uterus has been restored to its natural position, and kept there, the source of irritation of the nervous system will be removed, and the patient will get well. Anything that affects the nervous system injuriously interferes with nutrition, and when such irritation is withdrawn nutrition will go on regularly once more.

A CASE OF ATTEMPTED SUICIDE BY CHLORAL HYDRATE. SUICIDE BY CANTHARIDES.¹

BY FRANCIS F. BROWN, M. D., READING.

E. C. Q., aged forty-two, insane, phthisical, took with suicidal intent, on an empty stomach, eighty grains of chloral hydrate, December 17, 1879, about nine A. M. He was found snoring within five minutes after taking it. I saw him thirty or forty minutes afterwards, and found him comatose, breathing stertorously; twenty-four respirations per minute; pulse 80, of fair strength; pupils contracted. I gave him a teaspoonful of water, which provoked no effort to swallow; believing that emetics would be useless, even if swallowed, I concluded to wait and watch, as his respiration and pulse were good. At 10.15 both suddenly failed. The pulse became a feeble flutter, diastolic, scarcely to be counted, but I thought it was 100; respiration 21, increasing soon to 30. A few deep, snoring respirations would be followed by a number of shallow ones, in which the air seemed scarcely to enter the lungs at all. The tongue fell back, and partially obstructed the wind-

¹ Read before the Middlesex East District Medical Society.

pipe. I pulled it forward, shook him, and gave half a drachm of rum subcutaneously. The pulse slightly improved; the same dose was repeated in half an hour, and afterwards in drachm doses till one p. m., then every hour till three p. m., the last dose at five p. m. Nine drachms in all were given. This alarming condition continued a little more than an hour, from 10.15 to 11.30 A. M., during which time the tongue had to be kept pulled forward, and it seemed as if the heart and respiration would stop. At noon the respirations were 30; the pulse was 90, distinct, gradually falling to 68 at five p. m. After three p. m. he moved occasionally, and partially recovered consciousness at ten p. m., thirteen hours after taking the chloral, but he did not regain his speech till four hours later. The contraction of the pupils lasted about an hour, after which they were normal.

There are some points in this case which, though not unusual, are of interest:—

First. The suddenness of the soporific effect of the chloral. He had not been left more than five minutes when he was found snoring and unconscious.

Second. Absence of alarming symptoms for about one hour. During this time his pulse was 80, of fair strength and volume, and his respirations were 24.

Third. Sudden onset of the physiological effect of a poisonous dose of chloral, namely, failure of the heart's action and respiration, lasting about an hour and a half. Prof. H. C. Wood's *Therapeutics* speaks of *slowing* of the heart's action and respiration, as well as weakening of the same, as characteristic of chloral poisoning. Others do not lay so much stress on this effect, which in this case did not follow; but when the action of the poison was most marked the pulse was a rapid flutter, scarcely to be counted, dicrotic. After these alarming symptoms had subsided, the pulse was 90, gradually falling to 68 five hours afterward. His usual pulse lately had been from 75 to 80. The respirations, instead of being slow, as in opium poisoning, were quickened, ranging from 24 at first to 30 an hour or two later. Their alarming character was manifested in an entirely different way, as described.

Fourth. The good effect of hypodermic injection of alcohol was marked. Apparently it saved the patient's life.

Fifth. There was some anesthesia. Water did not provoke an attempt to swallow, and the needle punctures were not felt. The patient seemed as if a surgical operation would not rouse him, but I made no experiments.

The quantity of chloral requisite to produce death varies greatly in different cases. Forty-five and even thirty grains have produced alarming symptoms, and cases are on record in which so small a dose as thirty grains, and even less, has been followed by death. On the other hand, four hundred and sixty grains have been taken without fatal result.

Not satisfied with this the patient made another attempt on his life the next day, which was successful. Soon after eight A. M. he swallowed, on an empty stomach, half a pint of the following mixture:—

℞ Cantharidal colloidum	ʒi.
Sulphuric ether	ʒi.
Strong alcohol	ʒxvi. M.

This had been left by a former medical attendant for external irritation, and when somewhat freely used had produced vesication. I saw him in about half an hour. Attempts were at once made to excite vomiting. He

resisted strongly, and his jaws were set like a vice. We managed to pry his mouth open several times, and in all an ounce and a half of fluid extract of ipecac were poured into it. How much reached his stomach I do not know; probably but little. Considerable time was thus occupied. On account of this, and the further delay before a stomach-pump could be obtained, and the improbability that anything could be effected by it, I concluded that his fate could not be averted. He vomited between ten and eleven A. M., but mucus only. During all this forenoon, although he resisted us so strongly, he seemed in a semi-conscious state. Passed urine first at noon, and frequently and in considerable quantity—two quarts, his wife said—that afternoon. At first it was normal in appearance; then it contained something looking, I was told, jelly-like, or like the white of egg,—this I did not see; and finally it was bloody. In the evening it grew scanty, and frequent unsuccessful attempts were made to void it. He passed a little about midnight, none again till seven or eight A. M. and no more during the remaining twelve hours that he survived. The pain that he complained of most to me was over the region of the kidneys. That he said was severe. There was a good deal also over his bladder and the course of the left ureter, and scalding of the urine. No priapism. He never admitted to me, though repeatedly questioned, that he suffered in the stomach or bowels, but to his wife he said he was "burning" there. Mouth and throat were raw and sore, and from them he raised fluid freely, at first clear, later purulent and bloody. Signs of pain and distress did not make their appearance during the first forenoon; for four hours he lay quiet except when attempts were made to make him swallow. The pulse throughout was small, about 100, gradually growing weaker. The skin was cool; hands and feet tended to become cold. Opiates were freely used after signs of suffering made their appearance. He died thirty-five hours after taking the dose.

Autopsy, eighteen hours after death: present, Drs. S. W. Abbott and George E. Putney. Lungs contained tubercles, not softening; most in the left upper lobe, less in lower, a few in the right upper. Heart healthy, filled with fluid blood. (Esophagus, stomach, and duodenum inflamed; the two former deeply congested, the latter of a brownish hue. Bowels also congested, the redness growing less from above downward. Kidneys enlarged, the left larger than the right, intensely reddened, and gorged with blood. Dr. R. H. Fitz, who examined the specimens, found no evidence of fat in them. The interior of the bladder was reddened, and it contained two ounces of bloody urine. The liver and spleen were both gorged with dark blood, and the latter was somewhat enlarged.

— In commenting upon a death from chloroform, the London *Lancet*, instead of recommending the substitution of ether, says: "The lesson to be learned from accidents of this nature is that every operating theatre should always and constantly be provided with all the proper appliances to meet the fearful emergencies which, however rare [?], are liable to occur whenever anesthetics are given!"

— Says the *Western Lancet*: "All the homœopathic doctors ran away from Memphis on the appearance of the plague. Of the forty-six regulars ten did likewise."

Reports of Societies.

PROCEEDINGS OF THE NEW YORK ACADEMY OF MEDICINE.

ELECTION OF OFFICERS.

At the first meeting of the new year, held January 8th, the annual election of officers occurred, and among those chosen were the following: vice-president, Dr. Frank H. Hamilton; recording secretary, Dr. Edwin F. Ward; corresponding secretary, Dr. John G. Adams; and treasurer, Dr. H. P. Farnham. There was no election for president, Dr. Fordyce Barker's term having not yet expired.

On this occasion Dr. J. W. S. ARNOLD, professor of physiology and histology in the medical department of the University of New York, delivered an attractive address on

THE GRAPHIC METHOD AS APPLIED TO PHYSIOLOGICAL INVESTIGATION.

In commencing his remarks, he said that the graphic method, which within the last few years had been employed with such brilliant success in the field of physical science, had of late been adopted to such a wide extent in physiological researches that it would be quite impossible for him, in the limited time at his command, to describe or even allude to all its various applications in this department; but he trusted to be able to give those who were unacquainted with its advantages some slight idea of the method and the general manner of using it in these investigations. In the practical study of physiology it was frequently necessary to record a succession of acts, in regard to which, on account of their rapidity or the situation of the parts in which they occurred, it was impossible to make any accurate observations by means of our senses; but with the assistance of the graphic method, we were not only able to make observations of perfect accuracy, but also to record them in such a manner that we could study them at our leisure. The method was precisely the same as that now employed in all departments of science, and by it we were enabled to make definite measurements of the time and force expended in such acts.

The starting-point of the system was a space or distance moving in a horizontal direction past a fixed point in a certain period of time. This line in geometrical language was known as the *abscissa*. A line meeting this at a greater or less angle of inclination, according to circumstances, was known as the *ordinate*, and if the act which it represented were very rapid it would be at right angles, or nearly at right angles, with the *abscissa*; while if it were of a slow character, the angle described would be an oblique one. By studying the relations of the *abscissa* and the *ordinate*, which together constituted the coordinates, in the actions of the various portions of the economy, we could calculate almost anything in physiology. Especially could we thus obtain an accurate knowledge of muscular movements, and hence we had been able to determine much in regard to the heart and the circulation of the blood which had been hitherto unknown. This, however, was but one of the claims of phenomena which had been satisfactorily investigated by means of the method; and there were many others of equal importance or interest, such as the determining of the rapidity of nerve conduction and the time occupied by the brain in the exercise of its powers of volition and reason.

Dr. Arnold then proceeded to explain some of the applications of the graphic method, and some of the results that had followed these applications. The first essential was a traveling surface that moved at a uniform rate of speed, and this was most conveniently secured by means of a brass cylinder propelled by clock-work of great accuracy, which was regulated by a governor, and which could be made to go at a faster or slower rate, according as the observer desired. This cylinder, which was so arranged that it could be changed from a vertical to a horizontal position, served as the means of transmitting the various kinds of motion to the writer. The latter should be constructed to move with the least possible amount of friction. In this connection he described and exhibited the drum lever of Professor Marey, and pointed out the convenience of its application, as well as its other advantages. With this instrument such actions as the motion of the muscle of the ball of the thumb, and the movements of the elbow could be accurately recorded. For determining the character of the apex beat of the heart, a larger drum, fitted with rubber feet was required; and this enabled us to record both the rhythm of the heart and the respiratory movements at the same time.

In order to obtain accurate observations of the movements of the interior portions of the heart, Professors Marey and Cheauveau had successfully employed the cardiac sound, or cardiograph, which was introduced into the cavities themselves through an opening made in the jugular vein of a horse, and recorded the contractions of the auricle and ventricle at the same time. In certain physiological investigations it was found desirable to use a number of drums at the same time, and there was no difficulty about doing this, provided the writers or recorders were placed one above the other on exactly the same line.

Time measurement, Dr. Arnold continued, was always an element of great importance in such investigations, and the most convenient way of obtaining this was by means of the vibrations of a tuning-fork. Tuning-forks were not, however, always strictly accurate, and in order to be assured that the time measurement was correct in any case, it was necessary to verify the tuning-fork. This was accomplished with the assistance of a second pendulum, dipping as it swung into a little cup of mercury, which made and unmade a galvanic current, the battery furnishing which was in connection with an induction coil. In determining time it was sufficient to have an instrument delicate enough to indicate five hundredths of a second, as physiological action was quite slow in comparison with that frequently met with in the physical world. Thus, the process of thought occupied about one ninth of a second, while a flash of lightning was infinitely more rapid.

By this graphic method we were able, then, to secure definite observations in regard to form, the amount of force, the relation of one act to another, and the time occupied by various phenomena belonging to physiology. Dr. Arnold then explained the use of the sphygmoscope, the sphygmograph, the myograph, and various other instruments; after which the lights were turned down, and he exhibited numerous illustrations of these and the methods of employing them by means of the magic-lantern. Several of the representations were of unusual novelty and interest, such as the manner of accurately measuring the movements of the legs of a horse, and the flight of birds by the motions of the wings. By means of the myograph, the movements of the leg of a

frog, recently separated from the body and excited by a galvanic current, were then recorded in the presence of the Academy, and, with the assistance of the oxy-hydrogen light, the tracings, while being made, were beautifully thrown upon the wall. It was thus demonstrated that, while the movements under the electric stimulus were very rapid, the relaxation which followed these was more gradual.

In conclusion, Dr. Arnold remarked that the graphic method afforded us the means, not only of investigating much that still remained to be discovered, but also of confirming the correctness of what was already known. So much had already been learned through this instrumentality (especially in the Leipzig and Munich schools) that it was utterly impossible to study advanced physiology at the present time without a knowledge of the method.

The president, Dr. FORDYCE BARKER, in offering the thanks of the Academy to Professor Arnold for his brilliant and interesting address, said that such papers were of great service in fostering a love for science among its members, and in helping the institution to carry out its mission as a teacher in the profession. He did not doubt that some among the younger men present would be stirred up by the address to emulate its author's worthy example in the pursuit of scientific study.

PROFESSOR JOHN C. DALTON remarked that the chair had well expressed the indebtedness of the Academy to Professor Arnold for his lucid presentation before it of the graphic method, the adoption of which, he said, was undoubtedly to be regarded as almost, if not quite, the most important advance made in physiology during the last twenty years. By this means the physiologist had been enabled to determine a great variety of facts with a precision which could not otherwise have been arrived at. There was no question at all that Dr. Arnold was better acquainted with the method and had acquired more proficiency in its use than any one else in this vicinity, and perhaps in the country; and it had occurred to him that, possibly, on account of his own familiarity with the subject, the latter was inclined to underrate some of the difficulties which those less experienced might encounter in its practical application. For instance, *abscissa* and *ordinate* were rather formidable terms to the beginner, and some confusion was apt to exist in regard to them; but if we simply bore in mind that one represented movement and the other time, there would be no trouble about the matter. Seeing a thing, moreover, was always very much better than reading about it, and hence a practical demonstration like this was of the highest possible value. Thus, to see the law of falling bodies actually proved by the graphic method impressed it on the mind in a way that it could never be forgotten; and it was certainly of great interest to know that the same accuracy had been arrived at in the observation of physiological phenomena that had previously been reached in that of physical ones. In physiology there were such numerous movements, and so many variations of these, that it was utterly impossible for us fully to appreciate them by the senses or the mind; and it was well known that two individuals frequently differed entirely in the results of their observation of the same action, especially where several movements occurred in rapid succession. Under ordinary circumstances, therefore, the greatest incongruity must exist in the accounts of different observers; but, on the contrary, with the

graphic method absolute precision could be secured, because the record was made by the *thing itself* while it was actually taking place.

The only matter about which there was liable to be any source of error was as to whether in any case the instrument itself was strictly accurate; but so perfect had the method now become that the means were provided not only for correcting instruments, but also for ascertaining that such corrections were right. It was certainly a marvelous advance. Take, for instance, the cardiograph, he continued. It has always been supposed that the heart was the most delicate and sensitive of organs, and that any interference, however slight, would be followed by the most serious consequences. Yet by way of the jugular vein what is in reality a small walking-stick is introduced into its very cavities, and by this instrumentality their contractions are accurately recorded while they are actually taking place in their normal and regular order and intensity. Dr. Dalton had seen Dr. Arnold testing the cardiograph with the greatest facility in a horse, which was so little disturbed by the process that in the intervals between the experiments he munched his hay with the most profound satisfaction; and he did not doubt that the animal was still munching his hay, as good a horse as he had ever been before.

Remarks were also made by PROFESSOR MEYER, of the Stevens Institute, Hoboken, who is considered the greatest living authority on the correctness of tuning-forks, and PROFESSOR ROOD, of Columbia College.

Recent Literature.

The American Journal of Otology. A Journal of Physiological Acoustics and Aural Surgery. Edited by CLARENCE J. BLAKE, M. D., in conjunction with PROFESSOR A. M. MAYER, ALEXANDER GRAHAM BELL, PROFESSOR A. E. DOLEBEAR, of Tufts College, DR. ELLIOTT COUES, U. S. A., DR. J. ORNE GREEN, DR. A. H. BUCK, of New York, DR. T. SEXTON, of New York, DR. C. H. BURNETT, of Philadelphia, DR. N. H. SPENCER, of St. Louis.

The contents and the form of this journal recommend it as a decided acquisition to American medical literature. We know of no English or American medical journal that has given greater prominence to original scientific work, while its reviews and book notices furnish estimates of current otological literature that render it indispensable to the progressive physician. Indeed, the high character of the journal makes eulogy superfluous; the earnestness which characterizes the work of the editor and most of the contents of the journal leads us involuntarily to analyze a perception of lack of symmetry which we feel as physicians, while we are delighted as students. The result of our analysis brings us to the conclusion that the editors have placed rather too much stress upon the importance of physiological acoustics to the practitioner, and upon the anatomy and physiology of the ear to the physicist, in their attempt logically to connect aural surgery and physiological acoustics. An allusion to this point would be final, were it not that the success of the journal in the medical profession will depend, we think, upon correcting certain results which have followed the conscientious endeavor of the management to realize the purposes above alluded to, and expressed in the introductory as follows:—

"The work which is being done in the field of otology, and which is evidenced in the papers containing records of original investigations appearing in almost every scientific publication, and in the reports of the proceedings of scientific societies throughout the world, naturally suggests to the physicist the better appreciation of the structure and functions of the organ of special sense to the study of which his investigations in acoustics lead, and to the aural surgeon the necessity of overstepping what has usually been considered the boundary of his professional province by turning his attention to investigations in physics as the groundwork of his physiological and pathological studies, in order that he may be the better qualified to make that practical application of the knowledge to be so acquired in the conservative treatment of the various diseases of the human ear."

After examining the valuable papers of Professor Blake, of Brown University, Professor Mayer, Mr. Bell, Professor Dolbear, and Dr. Blake, contained in the present volume, we remain in doubt as to the advisability of making investigations in physics the groundwork of physiological and pathological studies; we feel rather like warning the practitioner from the danger of so doing; we would emphasize the imperfections of anatomy and physiology, and urge him to make direct observation in these branches the groundwork of his studies, to the end that his efforts may not be misdirected in attempts to harmonize physical truths with our present imperfect knowledge of the structure and functions of the ear, but that they may be turned to the proper professional aim of rendering this imperfect knowledge more complete.

The considerations that lead us to this opinion are not based upon theoretical grounds alone; they are partly founded upon the nature of the papers devoted to aural surgery in the present volume; these, with a few exceptions, notably those of Drs. Green and Burnett, do not appear favorably by the side of the careful and original observations contained in the papers devoted to physiological acoustics, while the anatomical and physiological contributions of Drs. Cones and Hunt are altogether too lonely.

Finally, we repeat our estimate of the scientific character of the journal and our heartiest wish for its success. Only a real desire that it may enjoy a long and vigorous life could lead us to appear almost ungracious in expressing our hope that in the future more of anatomical and physiological research, and a higher degree and greater amount of clinical observation, may furnish a better balance to the work of research in physiological acoustics. D. H.

Studies relating to the Curability of Insanity. By PLINY EARLE, A. M., M. D., Superintendent Northampton Lunatic Hospital.

These studies are extracted from Dr. Earle's last report, and offer further proof of the propositions contained in his paper on The Curability of Insanity, also a reply to Dr. Ray's rejoinder, entitled, *Recoveries from Mental Disease*. By diligent inquiry Dr. Earle follows out the subsequent history of twenty-five patients reported "recovered" in the Worcester Lunatic Hospital Report for 1843, and finds that eighteen of them had one or more subsequent attacks, seven having already died insane. The result very nearly approximates the formula of Dr. Thurman, of the

York Asylum, England, based on two hundred and forty-four persons. He says that of ten persons attacked five die in the first attack and five get well. Of the five who recover not more than two remain well, and of the other three two die insane. This is the most unfavorable estimate which has ever been made.

Dr. Earle says his object is to show that the popular belief in the great curability of insanity is not founded on facts. If such a pleasing delusion exists, it is questionable whether it is worth while to disturb it, especially when it is known that recoveries from repeated attacks are, by his own showing, extremely common. There is certainly some encouragement to be gleaned from the fact that patients recover from once to thirty-five times! Dr. Earle is deserving of credit for studies which tend to show numerically what all those familiar with insanity have known,—that there is a strong tendency to recurrence. But it is not necessary to estimate the curability of insanity on the basis of absolute immunity from future attack. No other disease is so treated in our general hospital statistics. Acute rheumatism, for instance, may be recovered from many times, and each recovery is satisfactory to the patient and creditable to the hospital. The chief objection to enlightening the public as to the danger of recurrence in recoveries from insanity is its disheartening effect on the patient, and the new weapon it puts in the hands of unfeeling, or rather unreasoning, opponents of hospital treatment.

The portion of these studies devoted especially to Dr. Ray's essay we leave to the great experience and skillful pen of Dr. Ray himself. We do not see any very broad disagreement between them. Both admit that reported percentages of recovery have diminished within the past thirty years. Dr. Earle thinks the temperament of the superintendent, and more especially the reporting of cases as if they were persons, will account to a great extent for the change. Dr. Ray thinks that the operation of these causes has been so constant to the present time as not to have much effect. He thinks the growing custom of admitting all forms of chronic and incurable mental disease, often complicated with organic brain disease, necessarily fatal, as well as a supposed decrease in curability from diminished vitality in our day, more probable causes of less frequent recoveries. Dr. Earle admits the above facts, but still claims, with perfect justice, that the frequent recurrence of insanity in persons reported as recovered reduces the percentage of persons permanently cured much below that of cases reported "recovered" in our hospital reports.

Dr. Earle accounts for the large percentage of recoveries in some of the Western hospitals by the probably large number of dipsomaniacs in them. His opinion rests on the hypothetical insane asylum of Mr. Henry W. Lord, secretary of the Michigan State Board of Charities and Correction, who in a recent pamphlet (*Hospitals and Asylums for the Insane*) assigned from thirty to fifty insane drunkards to a hospital for six hundred patients. This would be from five to eight per cent., which is a vastly greater number than our Massachusetts hospitals contain. T. W. F.

—The London Hospital on Christmas day received from a lady, who left it anonymously in an envelope at the porter's gate, the handsome gift of £5000.

Medical and Surgical Journal.

THURSDAY, JANUARY 29, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, OSGOOD AND COMPANY, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, OSGOOD AND COMPANY, Boston, Mass.

REPORT OF THE HEALTH OFFICER OF THE PORT OF NEW YORK.

OBSTRUCTIVE QUARANTINE.

DR. S. O. VANDERPOEL, health officer of the port of New York, has recently sent in to the commissioners of quarantine a valuable report characterized by a great deal of sterling common sense, which is largely devoted to the important subject of the purification of infected vessels, and in which he contends that the methods for accomplishing this which have been most prominently urged, if carried out, would involve much unnecessary expense and time, and would in effect make an obstructive quarantine. He first gives an interesting *résumé* of the history of yellow fever during the past season. The number of foreign ports at which it prevailed as an epidemic, together with its fatality in a portion of our own country, called, he says, for unusual vigilance on the part of the sanitary authorities. So persistent has been the disease in some of these ports, especially those of Hayti, that until the first of the year the arrival of vessels having had the disease during the passage or bringing it to the port was almost a weekly occurrence. Ninety-five vessels entered having had yellow fever on board either at the foreign port, on the passage, or in quarantine. Two hundred and fifty-six cases were reported as having occurred on these vessels. Twenty-nine cases were at quarantine hospital, of whom eleven died. There were, in addition, twenty cases of malarial fever, resembling yellow fever so much that it was deemed injudicious to pass them up to the city. The constant presence of yellow fever at some one of the West India ports renders its yearly recurrence liable at every port upon our extensive sea-board. Few arrivals of cases of small-pox occurred during the year, — seven in all; the medical inspection of emigrants when embarking on the voyage having almost destroyed this once prolific source of infection.

After speaking of the necessities of commerce at the present day, which demand the most active interchange of commodities, and require that the interests of the shipper shall be interfered with as little as is compatible with the public safety, Dr. Vanderpoel goes on to say: "To accomplish this purpose and enable suspected vessels to return to commerce with the least possible delay, various measures have been proposed, all, of course, having in view the destruction of the infectious element. The fact that this element has so far been intangible, and that all hypotheses for its destruction must rest alone upon its natural history and modes of transmission, render all suggestion more

or less experimental. So far as my observation extends, all the proposed methods with which the papers of the day have teemed for some time past have been advanced by gentlemen whose knowledge of the subject has been mostly hypothetical, and who had never been brought in close practical relations with the peculiarities of vessels, their varied construction, and the delicate relations of commerce and trade with any particular locality. The three methods prominently urged, both in the public prints and before legislative bodies, are, first, what is termed the refrigerating process; second, that by superheated steam; and, third, that of sealing a vessel and pumping in large quantities of air, so that by a process of oxidation morbid elements should be destroyed.

"It is not my purpose to discuss the merits of either of the above-proposed methods. For the sake of argument I am willing to admit that either might accomplish the desired purpose, but must contend that from a sanitary or commercial stand-point they are all impracticable and unnecessary. They are impracticable both on the grounds of time and expense. I assume that the aim of the promoters of these measures is to facilitate the return of vessels to commerce; and yet, in a port with the volume of commerce of New York, it would practically create an obstructive quarantine. In every branch of shipping and commerce time enters as one of the most important factors of success. To delay a steam-ship for successive trips, with its enormous expenditure of maintenance, is practically to abolish the line. Now, what would be the working of either of the above systems at this port? During the greater part of the quarantine season there are seldom less than twenty or thirty vessels discharging at the same time, under quarantine regulations. The use of either of the proposed methods contemplates special apparatus and trained men to place it in the vessel to be purified. Under the most speedy application, to make the work reliable, this would occupy a time of two or three days, and a further period of two or three days to render effective the destruction of the germs. But a single vessel could be treated at once; so that by the time the daily average could be rendered available for commerce, or safe to come to this city, the whole season would have passed, a moiety of the vessels only having been reached. But even if the time, by constructing a number of freezing hulks, could be lessened, another element quite as obstructive arises, — that of expense. The margin of profit arising from a single cargo from the West Indies is relatively small, and the success of the commerce is dependent, in a great measure, upon the extent of the port charges. There are of necessity additional expenses to a vessel discharging in quarantine above those of a vessel allowed to dock, and if to these be added an expense inseparable from such means of purification, the aggregate would be so onerous as to cause, in reality, an obstructive quarantine. I have not the data to estimate the precise cost of such a proceeding, but it could not fall short of two or three hundred dollars for each vessel, while it would require beside all the means of preliminary cleaning

now in use. Methods, therefore, which involve additional delay and expense become as obstructive as if the vessel were subjected to the traditional period of forty days."

In the above it is assumed that the refrigerating process would in all instances be successful; but from his extended experience in observing the varied construction of vessels, Dr. Vanderpool is led to entertain serious doubts upon the subject, and by going into a number of details concerning ship-hulls shows conclusively that there is very good reason for the existence of this doubt. But admitting, he continues, that freezing can be thoroughly effected, what certainty have we that it does more than render dormant or torpid the infectious germs? Analogy tells us that many of the forms of organic life are speedily vivified when, after freezing, they are cautiously exposed to warmer media. Recent experiences would also seem to show that, while the cold of a Northern winter will render dormant the infection of a yellow-fever vessel, the disease will reappear as soon as the vessel passes into a temperature favorable for its propagation.

Serious and doubtful inefficiency as would be the protection from the employment of the above systems, Dr. Vanderpool then urges the further objection that they are unnecessary; and states that he regards as practically efficient the measures which now prevail at the port of New York, and which have been published in number nineteen of the bulletins of the National Board of Health. After making this statement, he anticipates what at first sight would seem to be a valid objection to the efficiency of these measures. In July of the past summer a bark arrived from Havana with sickness on board, and with a history which plainly pointed to an infected ship. The methods of purification which had up to that time been those wholly relied upon were faithfully applied, and, when completed, permission was given to the vessel to come up to the city. After the vessel had been at dock in a very foul locality for ten days, a case of yellow fever occurred in the person of the stewardess; the vessel was then ordered back to quarantine, and a very thorough exploration was made of her. Up to that period, Dr. Vanderpool explains that he had been led to suppose that "limber holes" were a reality, and that when the pump threw out absolutely clean water the bilge was perfectly clean; so that he had never required the limber streaks, as they are called, to be taken up, in order to examine the spaces between the timbers. When the vessel was examined, after her return to quarantine, all her cabin and hull were apparently as clean as could be; but when, with great difficulty, the limber streaks were taken up, masses of filth were found between each frame. After a second purification no other case occurred on the vessel. So, too, one of the regular Havana steamers, though to all appearances as clean as it was possible to make her in every part, still brought in cases of fever on nearly every voyage. After the above experience it was ordered that the limber streaks should be taken up the entire length, and here the limber holes were found to be in frames two inches from the floor and

containing more or less filth. After thorough cleansing, cement was put between each frame to the level of the holes, and no case of fever has since arisen on the vessel.

Finally, Dr. Vanderpool expresses the opinion that no refrigeration or dry steam could insure safety without the careful preliminary purification upon which he insists, and that if this is faithfully carried out, and the prolonged use of sulphurous acid gas thoroughly resorted to, it will reach every secret cranny quite as effectively as the more expensive and elaborate methods.

There is some reason to apprehend that the new governor of New York, with his well-known preferences for homoeopathy, may appoint a practitioner of that school as health officer in Dr. Vanderpool's place; but it is to be sincerely hoped that sufficient influence will be brought to bear upon him to induce him to retain the latter in a position which he fills with so much honor to himself and such evident benefit to the community. As an evidence of the appreciation with which his experience and services are regarded in New York, the fact may be mentioned that all the officers of banks and every firm engaged in commercial business in the city have signed a petition to Governor Cornell asking his retention in office. There may perhaps be no great harm in appointing a homoeopath from an inland town to a merely nominal position, like that of surgeon-general of the State; but to fill the important and responsible one of health officer of the port of New York in the same way would be so unwise a measure that its results would probably prove most disastrous to the public welfare.

DIPHTHERIA: A CIRCULAR OF THE BOSTON BOARD OF HEALTH.

THE Boston Board of Health has issued a circular, which was also published in the daily papers, "for the purpose of more widely extending the knowledge of a few well-attested facts concerning diphtheria, and reminding all persons that greater care should be exercised to prevent the spread of this much-dreaded disease." Such a compendium of the most approved views in regard to prophylaxis and disinfection against a disease so constant and fatal as this is always timely, and cannot fail to be useful. Although the inhabitants of Boston, as of other parts of the country, have, unfortunately, such frequent and sad opportunities of becoming acquainted with the sources, the modes of propagation, and the tenacity of life of the diphtheritic poison, there are doubtless large numbers who will be reached by this circular who are still ignorant of many of the important points which it insists upon, and others who, though knowing, neglect to remember them. There is of course in all cities a large population whom it is impossible to reach by circulars or any other device, and who will continue to do as they have done.

How considerable a factor diphtheria is in the death lists all over the country can be easily seen by consulting the very valuable weekly mortality reports,

which, by the courtesy of the State Board of Health, we are enabled to publish even in advance of those issued at Washington, and whose accuracy (as far as that quality is attainable) and general value cannot be too highly commended to our readers.

No such statistics can do more than approximate to their possible value, until urban populations are accurately estimated and the real causes of death more carefully recorded. Under no disease, probably, are there so many ignorant and purposely perverted death certificates as under diphtheria. We wish it were in the power of the Boston Board of Health to grant some degree of protection against this, and sincerely hope that it may, in the course of another year, find itself in a position to exercise some authority in this particular.

The last paragraph of this circular, we are glad to see, gives emphatic expression to the opinion that "no public funeral should ever take place at the house where the patient died, nor elsewhere, unless the coffin remains hermetically sealed."

MEDICAL NOTES.

—The expenses of the National Board of Health to January 1, 1880, amounted to \$154,002.42, a little over one fourth of the appropriation, which was \$550,000.

—The United States senate has confirmed Dr. Philip S. Wales as surgeon-general of the navy.

—In the state legislature a petition has been presented by Robert Treat Paine, Jr., and others, a committee of the health department of the American Social Science Association, that all persons be prevented from practicing any branch of medicine in this State except such persons as have furnished to the authorities of the State sufficient evidence of good moral character and of the possession of a thorough knowledge of their duty and calling.

—From the annual report of President Warren, of Boston University, it appears that there are one hundred and forty-six students in the School of Medicine, of whom fifty-two are females. It is denied that this school is exclusively under the control of the homeopaths. To what extent this emancipation has been carried we are unable to learn; not very far, we think. "The Homeopathic College of Physicians and Surgeons, Modern School," is the title of a new medical college in Buffalo. The "modern school" means that, together with homeopathy, pure and simple, will be taught the uses of drugs in ordinary doses, such as "the experience of ages has proven remedial."

—Mr. Manders says in the *Lancet*: The prognostic value of herpes labialis in pneumonia has greatly interested me during the last two years, since hearing a remark made by Dr. Broadbent that herpes was invariably preceded by rigors. In every case I have seen since I have found this true, though I have observed that the crop of herpes bears very little relation to the amount of rigor. From this I was led to investigate the phenomenon in other cases where the

nervous system has received a severe shock, and soon had the opportunity of watching over fifty cases of internal urethrotomy. In the majority of these cases rigors took place, and were invariably followed by a crop of herpes, whereas in those cases where no rigors occurred herpes was absent. As in pneumonia, it added very little to the prognosis.

—From the annual report of the treasurer of Harvard University we learn that the Medical School has made a surplus of \$16,763.29, chiefly from increase in the fees from students. Of this amount, however, the sum of \$7223.22 is due to a change made in the form of account, by which all term-bills issued for the year are credited to the school, whether paid within the year or not. The actual surplus would therefore be about \$9500. Hereafter the receipts reported from tuition fees will correspond with the number of students in the school during the year, and not with the bills actually paid within the year, as heretofore. This change makes the Medical School account conform to those of the other departments of the university, and to it is due the large increase in the item of advances for unpaid term-bills. In 1877-78 the surplus of the Medical School was \$3603.61.

In the Dental School, a great reduction of expenses, chiefly in salaries, has made a surplus of \$188.04, which has gone to reduce the debt of the school. In 1877-78 there was a deficit of \$2245.24.

—The house committee on agriculture considered the propriety of memorializing Congress for the passage of a law to prevent the spread of pleuro-pneumonia among cattle.

—We are glad that the *Galveston Medical Journal*, Dr. Greenville Dowell, editor, has reappeared after several years' suspension, "owing to three fires, bad health, and confidence in promises." Having learned wisdom by experience, the editor candidly says, "We do not expect to make money out of its publication, and when it will pay expenses and have any surplus we will increase the number of pages. We edit it for the exchanges and books for review, to which we will give close attention." There is a circulating medical library in connection with the journal.

—M. Mahovsky, a Russian physician, having remarked the frequency of short-sightedness among literary men, suggests that books be printed in white ink on black paper. He has made experiments upon fifty individuals which seem to confirm his view.

—The White Mountain Medical Association will hold its next annual meeting at Wells River, Vermont, on the 28th and 29th January, 1880. This society includes the medical men of those counties bordering upon the Connecticut River from Hanover, N. H., to Canada.

NEW YORK.

—The Sanitary Reform Society, which consists of such men as Henry E. Pellew, Judge Daly, William E. Dodge, Jr., Dr. John T. Metcalf, O. B. Potter, and James Gallatin, have lately had a conference with the board of health, represented by the president, Dr. Charles F. Chandler, and Commissioner Edward G. Janeway, in regard to the operations of the tenement-

house act and other sanitary matters. Last winter there was considerable agitation on the subject of tenement-house reform, and two or three large public meetings were held for the purpose of promoting the object. Since then very gratifying progress has been made in the matter, and on the first of December last the above society was organized; its object being to aid in improving the sanitary condition of the city, and especially the dwellings of the poor. At this conference Dr. Chandler reported that in four months two thousand tenement-houses had been officially visited by the sanitary inspectors, appointed under the provisions of the tenement-house act, and that a ledger account had been opened with each house. All new houses, he stated, were now built strictly in accordance with the requirements of the law. At the commencement nearly every plan had to be rejected; but now architects and builders, better appreciating what was demanded of them, and recognizing the authority of the sanitary department conferred by the legislature, were much more careful to comply with the rules laid down, and at least two thirds of the plans submitted were immediately approved. Many owners of property had come before the board to complain of the supposed injury to their interests thus occasioned; but were soon convinced, as a rule, that the suggestions made were really for their benefit, as well as that of the community at large. The sanitary police, Dr. Chandler continued, reported an average of one thousand seven hundred nuisances a month; but their complaints were generally heeded, and nuisances abated without hesitation. He further spoke of the importance of sanitary reform and active surveillance by the department to the mercantile community, the success that has attended the work of the vaccinating corps, the immunity from serious epidemics that the city has enjoyed, and the gratifying results that followed the house-to-house visitation of the tenement districts during the summer by the special physicians appointed by the board. He regretted, however, that the appropriation of 1879 had been cut down for the present year, and that they would thus be crippled in carrying out sanitary work which had been proved to be of vital importance.

— At this season many entertainments, public and private, are given for the various charitable institutions of the city. The principal of these the present year are the "Martha Washington Reception," in aid of Saint John's Guild, the Charity Ball, in aid of the Nursery and Child's Hospital, and the Purim Ball, in aid of the Mount Sinai Hospital and Dispensary, — all of them being held at the Academy of Music. The first of these came off on the evening of January 20th, and the receipts are to be appropriated to the establishment of a permanent sea-side nursery, to which frequent trips may be made during the summer by the "floating hospital," which has already been in successful operation for some years. The sanitary superintendent, Dr. Day, has written a communication to the officers of the guild, in which he alludes to the happy results which have attended the excursions of the floating hospital, and expresses the opinion that all that

can be said as to the usefulness of the latter applies with double force to a permanent hospital on the seashore, for the relief of the sick children of the poor.

PHILADELPHIA.

— The Philadelphia County Medical Society held its annual meeting January 21st for the election of officers for the ensuing year. Sixty-six members were present. Reports from the board of censors and auditing committee for treasurer's accounts were presented and read by Dr. L. F. Baldwin. Reports were also received from the treasurer, recording secretary, corresponding secretary, assistant recording secretary, and reporting secretary. The publication committee also presented a report for the past year.

The following gentlemen were elected for the respective offices for 1880: Albert H. Smith, M. D., president, John H. Packard, M. D., vice-president. H. Lenox Hodge, M. D., vice-president. J. G. Stetler, M. D., censor. William M. Welch, M. D., treasurer. Charles B. Nancrede, M. D., recording secretary. J. D. Nash, M. D., assistant recording secretary. William Goodell, M. D., corresponding secretary. Frank Woodbury, M. D., reporting secretary. M. O'Hara, M. D., librarian. Drs. Henry H. Smith, Richard J. Dunglison, and J. Howard Taylor were elected delegates to the convention to revise the National Pharmacopœia, to be held in Washington in 1880.

A resolution was adopted, and referred to the committee on hygiene and the relations of the profession to the public, setting forth the present unsatisfactory method of committing the insane to the charge of a hospital, and recommending legislation upon the subject in order to relieve physicians in the discharge of their duties from the annoyance and expense of defending themselves from a criminal charge.

— A stated meeting of the Academy of Surgery was held in Philadelphia, January 5th, and a permanent organization effected by the election of the following officers to serve during this year: President, Samuel D. Gross. Vice-presidents, D. Hayes Agnew and Richard J. Levis. Secretary, J. Ewing Mears. Corresponding secretary, Thomas G. Morton. Treasurer, William Hunt. Reporter, John B. Roberts. The council is made up of five members, the president, recording secretary, and treasurer, to which were added John Ashhurst, Jr., and John H. Brinton. The publication committee consists of W. W. Keen, John H. Packard, and the reporter. S. W. Gross was chosen pathological histologist. Professor Gross, upon taking his seat, expressed his deep interest in this society, which had long been a cherished project in his mind. He made a donation, as a nucleus for the library, of handsomely-bound copies of his own writings, which he said he offered as an earnest of a larger donation that he hoped to make at the proper time. Dr. Adinell Hewson presented a letter of historical interest to the society, written by John Morgan, one of the early pioneers of medicine in the country.

— At the last meeting of the board of managers of the Pennsylvania Hospital, on recommendation of

the medical staff, a resolution was adopted directing that no cases of fracture should be dressed unless they are willing to remain until examined by the attending surgeons, who will decide whether they should receive treatment in the wards, or by applying at the out-patient's department. One of the advanced ideas that was broached at the same meeting was that the hospital be placed in telephonic communication with the offices of the medical staff. This question was referred to a committee, with power to act, with every prospect of its being speedily accomplished.

—It seems particularly difficult to bring a certain class of malefactors to punishment in this country, although in England they are dealt with quite stringently. A notorious abortionist, having carried on his trade successfully in this city for years, was finally caught in *flagrante delicto*, literally red-handed. A young married woman left her home early in the evening to go to the doctor's office, and as she did not return soon her husband came after her, and found the victim dead, and the "operator" trying to revive her with a galvanic battery, in which he was unsuccessful. The implements used for producing abortion were scattered around, and were secured by the police. The coroner's examination revealed the fact of the attempted abortion, and probable entrance of air into a uterine sulcus. The case was clearly made out, and a verdict of guilty was promptly rendered. The judge gave the specialist a sentence of *two years*, because evidence had not been offered to show that he was a professional abortionist, and because, forsooth, the poor victim was a married woman. Since then another case of death has occurred, from medicine ordered for the purpose of producing a miscarriage, in the "practice" of an Indian doctor, so called; but he was promptly haled out, and is not very apprehensive of having his business injured, but on the contrary it will serve as an advertisement for him.

—In connection with the latter case a very discreditable charge has been brought against one of our leading drug houses. This charlatan advertised freely, and offered on certain days to treat the poor *gratis*. Those who took the bait and applied for treatment were given a prescription that could be filled only at one place, the establishment in question. On reaching the drug store they learned that the medicine would cost from two dollars and a half to three dollars, or more; if they subsequently applied at any other store they could not get any one to decipher the prescription. Thus the *prima facie* evidence of collusion is strongly made out. So the old game goes on all around us, and yet physicians are too cowardly or indolent to make their influence felt in an unmistakable way in condemnation of such practices, which should not be tolerated for a moment. A few vigorous prosecutions for conspiracy to defraud would clear the moral atmosphere amazingly.

—Professor Gross was the recipient of the honor of a complimentary dinner on the 14th instant, given in New York by Prof. Austin Flint, at which only a select few were present. The compliment was keenly enjoyed by the veteran professor, who is in his element when in the congenial society of his friends.

Miscellany.

ANTISEPTIC SURGERY.

LECTURE BY PROFESSOR LISTER.

QUITE recently, and probably as a reply to objections to his system, which were read by an English surgeon at the last annual meeting of the British Medical Association, Professor Lister gave an interesting lecture in illustration of antiseptic surgery. He made use of two typical cases. The first of these was a case of empyema. The patient, a little boy, from whose left pleural cavity Lister had evacuated, three weeks previously, a large quantity of thick, yellow pus by means of a free incision in the infra-axillary region. Lister removed a dressing which had been applied three days before, not because of a need of so doing, but in order to show the boy's condition. It was removed under spray, and was found to be dry. A silver drainage tube was also withdrawn, because obstructed by lymph. The boy was then turned upon his side and the pleural cavity completely emptied, this issue being, not pus, but a single ounce of serum, which, Lister claimed, strikingly illustrated the effects of antiseptic treatment. "For," said he, "I venture to say that this purely serous accumulation could not have occurred without antiseptic management." Primarily the left pleura was distended with pus, the heart being dislocated far to the right. Aspiration had been repeatedly practiced by the boy's physician, the result being that usual in empyema, — reaccumulation of the fluid, and that fluid always yellow pus. Lister then opened the cavity by free incision antiseptically, and from that time no purulent discharge occurred. This result, according to Lister, could not have been obtained without compliance with two conditions, namely, affording free drainage to the fluid, and at the same time preventing the access of putrefaction. "Aspiration," said Lister, "removes tension for the time being, affording only insufficient relief; for the fluid soon reaccumulates in amount sufficient to reproduce decided tension, and that tension, acting in a reflex manner through the nervous system, brings about inflammatory excitement of the pyogenic membrane, into which the pleura has been converted by disease, and so reproduces suppuration, as it has been previously maintained. We must therefore afford permanent relief by free drainage. But if, at the same time, we had not adopted efficient antiseptic means, we should have had a continuance of suppuration, because, though tension would have been prevented, the irritation of putrid liquid would have stimulated the pyogenic membrane to pus formation. In the present case the accidental accumulation shows in a perfectly indubitable manner that the fluid effused was serum, not pus. This is an illustration of the beautiful pathological truth that a pyogenic membrane, when freed from irritation, ceases to suppurate. Had I shown a dressing soaked with serous discharge, you might have thought, 'Are we sure there is not here some pus, masked by some action of carbolic gauze upon it?' But when you have the unmixed serum before you, there can be no mistake whatever." Lister then said that under the antiseptic treatment the boy's health had markedly improved. The means adopted were the following: First, the skin was well washed with a one-to-twenty solution of carbolic acid. This has the power to penetrate the epidermis and hair follicles, and any greasy matter which may be upon the skin. To wash with soap and water, and afterward with ether, as the Ger-

mans do, is unnecessary. Secondly, hands and instruments were cleaned with the same lotion, and the opening into the pleura was made under a thoroughly trustworthy carbolic spray. "This severely tests and demonstrates the efficacy of the spray, because with every inspiration air is drawn into the pleural cavity. In managing an adult, we can say, while making the incision, 'Hold your breath; also while removing the dressing. But we cannot control the respiration of a child. It is therefore necessary during the manipulations that we have a reliable apparatus for the production of the spray, and also that there shall be no chance of any air other than spray being introduced." Empyema being, therefore, a disease requiring very great care in the use of the spray, and since the pleural cavity again and again was filled with spray during the three weeks of treatment, Lister claimed that the case offered as good evidence as a laboratory experiment of the power of the spray to correct the septic property of the atmosphere, or, in other words, "to destroy the energy of the septic ferments which the atmosphere contains." Thirdly, carbolic gauze was used as a dressing. Lister has lately improved the gauze. He formerly used one part of carbolic acid, five parts of common resin, and seven of paraffin, the latter being used to prevent adhesion. He now uses one part carbolic acid and four parts each of resin and paraffin. This gives a large proportion of carbolic acid. But the new dressing is not irritating. Lister therefore considers the modification a great advance. On the whole, too, the new combination is less expensive than the old. The paraffin should be *pure*; otherwise it will act on the mackintosh cloth. Its lessened quantity causes more adhesiveness, an advantage according to Lister.

The gauze as usual was applied in eight layers, a piece of mackintosh being placed under the outer layer. A large quantity of gauze in loosely folded pieces was also used underneath the dressing, because of the copious flow of serum from the pleural cavity. In the adult these dressings must be changed twice daily, but in the child, the discharge being less, it was changed but once in the twenty-four hours. The dressing was kept in place and its edges in apposition with the skin by an elastic bandage applied around them. This Lister considers a great necessity. An india-rubber tube was employed for drainage, but its ordinary use was modified by the introduction of a mass of carbolized gauze into the two loops of silk connected with its orifice, in order to prevent the suction of the tube into the pleural cavity. In the course of a few days, as is common in cases of empyema treated by drainage, the thorax contracted, the ribs approached each other, and compressing the tube arrested the discharge. In consequence a silver tube, three fourths of an inch long, with a metal collar, a rounded end, and holes in its sides, was substituted.

It is frequently the custom in Germany to cut away a piece of the rib to insure drainage. This Lister never does if the metallic tube can be inserted sufficiently early. He remarked that at Amsterdam he was surprised to learn that some surgeons consider carbolic acid so poisonous to young children that it should not be used for them. In the case in question the child was but three years of age. He had been enveloped in carbolic gauze from armpits to pelvis, but had suffered no constitutional effects whatever. In explanation of the carbolic-acid poisoning in German cases, Lister said he believed his immunity from toxic effects

was due to careful avoidance of all unnecessary action of the carbolic acid upon the tissues. Some persons inject carbolic lotion into the pleural cavity at every dressing. Continental surgeons, after stitching a wound together and putting in drainage tubes, inject with a syringe a one-to-twenty solution through the tubes; again, in changing antiseptic dressings, some surgeons syringe out the wound. This, Lister thinks, is not only superfluous use of the carbolic acid, but a practice which, in every such case, exposes the patient to the danger of absorbing the carbolic acid into the circulation, perhaps in great abundance. Nevertheless, he does not deny that in rare idiosyncrasies there may be carbolic-acid poisoning in spite of the avoidance of its needless introduction into the system. This point he illustrated by an allusion to such a case. If such an occurrence should show itself, he would advise the immediate application of the boracic-acid dressing. But in deep-seated affections, like empyema, we should not trust to this mild boracic acid. Lister believes the best substitute for carbolic acid to be salicylic acid, first introduced into surgical practice by Professor Thiersch, of Leipzig. It may be used in the form of salicylic jute, a reasonably cheap material. Lister mentioned a case of empyema in which this dressing had been used under the carbolic spray with a successful termination of the case. The jute must be applied in quite large mass, and Lister advises the use of mackintosh outside to prevent the discharge soaking through it.

(To be concluded.)

EXAMINATIONS FOR COLOR-BLINDNESS.

BY DR. HUGO MAGNUS, BRESLAU.

THE great importance which color-blindness, or the congenital lack of sensibility to certain colors, possesses in relation to railroads and the safe navigation of vessels is now pretty well recognized over the civilized world. To accomplish the diffusion of this knowledge has cost much labor and the overcoming of many difficulties. It is due to the unremitting efforts of writers of high repute, who have thus finally gained the attention of the authorities to this subject of color blindness.

For the safety of the public traffic this is a very important question, not only that all authorities should turn their attention to the defect, but that they should seek practically the means of definitely counteracting the growing danger arising from color-blindness. When a government or an authority or corporation has earnestly determined to apply some safe control, two questions at once arise as to the control itself. These two points, to be presently explained, are of such paramount importance that it may not be valueless to hear the criticism of them by an expert who has made a careful study of this defect. The two questions are. —

First, who shall carry out the examination of the railroad and marine personnel?

What methods are to be employed?

Now as to the first question. Who are to conduct the tests?

Here we must express ourselves most decidedly and most earnestly that under all circumstances this should be done only by those capable and experienced, and such are, in the largest majority of cases, ophthalmic surgeons. We do not hesitate to say that on the proper choice of those who are to carry out the test

its whole success depends. If the authorities make a mistake in this choice the value of all the examinations is but questionable. Moreover, the security which the community feels from these tests is undermined. If the examination of the railway personnel is to be of value, the railroad authorities must look to it most carefully that this is placed only in the hands of such persons as from their special knowledge are fitted to undertake it. The examination by medical experts alone guarantees the requisite precision and the consideration of all the possibilities accompanying such examinations.

It might at first sight seem as if the testing the color sense was a very simple matter, and hence any official, without special knowledge, could be instructed in it. Such a supposition is, however, a grave error, and liable to lead to practical results most dangerous for the life and limb of the traveling public. We grant that testing for color-blindness offers no very great technical difficulties; but it must be remembered that in these examinations is presupposed the very extended information which alone specially instructed persons can possess, and such are only experienced ophthalmic surgeons. To determine with absolute accuracy whether an individual has a normal color sense or not, one must be familiar with the indications of the normal sense of color. The abnormal, or, as is said in medicine, the pathological, can only be correctly interpreted when the normal or the physiological is thoroughly understood. An extended knowledge of physiology is needed thoroughly to appreciate the abnormal or diseased condition. Without this a knowledge of the abnormal is but artificial and second-hand, liable to be at fault on the first good opportunity. To intrust the testing of the color sense to one not medically educated is but giving scope to incompetent meddling. A man without medical education can have only the most scanty knowledge of the general characteristics of color-blindness, and never a true conception of the physiology of the color sense. The tests such a one will make can only be the most superficial. He can never examine with the accuracy necessary to meet the requirements of science under all circumstances. For such is needed the most careful preparation and a thorough knowledge of physiology. Moreover, examinations for color-blindness are not so simple and stereotyped as never to place the examiner in doubt and uncertainty. The examiner's knowledge of physiology is often most seriously taxed in his test of employees,—we mean when color-blindness is feigned. Our own experience with railroad officials proves most conclusively that cases often enough occur where one or another employee seeks to avoid by feigning the consequences of his detected color-blindness. An examiner who has only the superficial knowledge of the more marked practical indications will thus be completely at a loss. That such cases will often arise where the employees have learned that an examiner can be *talked over* and *persuaded* may well be believed without our special confirmation or assertion. Only the most perfect familiarity with the physiological and pathological functional expressions of the color sense can in these cases guarantee the perfect trustworthiness of the examination. Without this the result is but questionable, either from the employee's feigning or the examiner's ignorance. But all will grant that such uncertainty can never be allowed with the testing the color sense of the railroad personnel, where the practical conse-

quences are so dangerous. Such uncertain results will follow the authorities employing those who are not experts. A waste of the time and money the examinations have cost.

With so important a question as color-blindness for the security of railroad traffic, there can be no half-way measures; these will not protect from it. The fullest and most thorough attention is here needed. Let those who would put these examinations out of the hands of experts pause and consider the responsibility they are assuming.

In the interest, therefore, of the traveling public, we demand that these tests shall be carried out by ophthalmic surgeons. If now it is asked, Cannot any physician make them? we must answer in the negative, without desiring to question the knowledge of our colleagues. The practicing physician has so little opportunity to acquaint himself with questions of physiological optics that he is liable, just here, to be found wanting. What he has learned of these in his student's work will have been quite driven to the background by the cares and necessities of practice. When suddenly called upon to apply what he has once known, he finds himself lacking the so necessary certainty.

Any of our colleagues, upon serious consideration, will own that he hardly feels at home in the domain of physiological optics. We need not, of course, add that there are exceptions. We see, therefore, why the practicing physician is not in a position successfully to carry out such examinations. Practical experience has, moreover, proved this most conclusively. The German railroad surgeons, *not instructed in ophthalmology*, found a startlingly small per cent. of color-blindness among their employees. The ratios in Europe which at present are considered of any value were all obtained by the tests of ophthalmic surgeons or expert physiologists. We must therefore agree with Dr. Reuss, of Vienna, when he remarks "that examinations of this character [that is, not by experts] are *valueless*." Now, if practicing physicians are incapable of conducting these examinations, what results will the laity, who know nothing of medical science, obtain by their testing?

We sum up our claim by saying that, first of all, ophthalmic surgeons, being those who best understand the eye, shall test all its functions. If practicing physicians are to be called upon for this, they must first go through with a preparatory course of special study with an ophthalmic surgeon, to whom all their results are to be finally referred.

We can only consider a practicing physician prepared to undertake the very responsible position of examiner of railroad employees after he has had thorough instruction in the practical carrying out of the test, the nature of color-blindness, its forms, and its various characteristic appearances. And even then we consider the final control of an ophthalmic surgeon absolutely requisite. We are convinced that our colleagues who are practicing physicians will readily admit the truth of these propositions. Experience has abundantly shown us into what difficulties and perplexities a physician is plunged by the sudden call upon him for a knowledge of color-blindness which he never can have gathered in his practice.

Whilst we are not opposed to a practicing physician acting as examiner, provided he has been thoroughly instructed by an ophthalmic surgeon, and the final control and decision is left to the latter, we are entirely

opposed to employing those who are not physicians for this testing, no matter what instruction they may have obtained. The laity having no medical preparation, any attempted teaching them the functions of the eye will be but most imperfect; they can never thoroughly understand and appreciate them.

The final result of our argument is that the examination of the eyes, both for color-blindness and visual power, should be carried out only by educated and experienced ophthalmic surgeons. Where none such can be had, practicing physicians who have been especially instructed may be employed, but their results must be finally submitted to the control of the ophthalmic surgeon. The laity, that is, all who are not medical men,

are under no circumstances to be permitted to make these tests of the color sense and visual power.

Let us turn now to the second question, namely, What method of testing shall be employed? This we can very quickly answer. General experience has taught that the best method of testing is that of Professor Holmgren, of Sweden, and this method we would most strongly recommend to every railroad corporation. We would say in conclusion that the excellent book of Dr. Jeffries, of Boston, contains the necessary description and information. As we wholly agree with Dr. Jeffries upon the superiority of Holmgren's method, we would thus, not to render our argument too long, simply refer to his volume.

REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 17, 1880.

Two thousand one hundred and ninety-two deaths were reported; 842 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 326, consumption 315, lung diseases 310, diphtheria and croup 197, scarlet fever 74, typhoid fever 33, measles 29, diarrheal diseases 28, whooping-cough 25, malarial fevers 12, erysipelas 12, cerebro-spinal meningitis 10, small-pox six. The death-rate of whites in the District of Columbia was 17.33; of colored, 32.5. From measles, New York 19, Chicago three, Brooklyn two, St. Louis, Milwaukee, New Haven, Lowell, and Holyoke one. From whooping-cough, New York six, Brooklyn four, New Orleans and Pittsburgh three, Baltimore and District of Columbia two, Philadelphia, Chicago, Cleveland, Lowell, and Lawrence one. From malarial fevers, District of Columbia three, New York, Brooklyn, Chicago, and New Orleans two, Milford one. From erysipelas, New York four, Cleveland two, Philadelphia, Brooklyn,

District of Columbia, Milwaukee, Charleston, and Springfield one. From cerebro-spinal meningitis, New York four, Philadelphia, Baltimore, Boston, Pittsburgh, Pittsfield, and Chicago one. From small-pox, Philadelphia and District of Columbia three. There was one case of small-pox in Baltimore and four in the Marine Hospital in that city.

The total number of deaths, as compared with the previous two weeks, continues to decrease, while the deaths under five show a progressive increase. The mortality from small-pox and diphtheria is higher than in the previous week, the other diseases remaining about the same. In 26 cities and towns of Massachusetts, with an estimated population of 1,015,920 (population of the State about 1,550,000), the death-rate was 20.89 against 20.65 of the previous two weeks, the deaths from lung diseases and consumption being greater than in the previous week; from scarlet fever and whooping-cough less; no deaths from small-pox.

For the week ending December 27th, in 146 German cities and towns, with an estimated population of 7,594,042, the death rate was 27.5 against 26.5 of the previous week. Four thousand and twenty deaths were reported; 1762 under five years of age; pulmonary consumption 540; acute diseases of the respiratory organs 507, diphtheria and croup 183, scarlet fever 73, whooping-cough 67, measles and *röteln* 64, typhoid fever 61, puerperal fever 24, typhus fever two, small-pox (Cologne) one. The death-rates ranged from 10.4 in Karlsruhe to 46.1 in Erfurt; Königsberg 35.0; Danzig 29.1; Breslau 27.2; Munich 31.9; Nuremberg 27.7; Dresden 27.5; Berlin 25.2; Leipzig 23.9; Hamburg 28.8; Hanover 22.8; Bremen 22.1; Cologne 32.3; Frankfurt 27.2. For the same week, Vienna 28.3; Prague 41.3; Paris 32.1. In 48 Belgian cities and towns, with an estimated population of 1,480,405, 886 deaths were reported: bronchitis and pneumonia 169, pulmonary consumption 76, diarrheal diseases 44, small-pox 41, fever 14, whooping-cough 12, croup nine, measles six, scarlet fever three, diphtheria none. The death-rates were: Brussels 28.7; Antwerp 32.7; Ghent 20.2; Liege 34.7; 22 larger towns 27.3; 22 smaller towns 26.9. Small-pox and typhoid fever continued very prevalent in Paris and Marseilles.

For the week ending January 3d, in the 20 English cities with an estimated population of 7,383,999, the death-rate was 29.1 against 27.4 and 30.5 of the previous two weeks. Four thousand one hundred and twenty deaths were reported; 973 under one year; diseases of the respiratory organs 672, whooping-cough 241, scarlet fever 128, measles 125, diarrhoea 42, fever 40, diphtheria 27, small-pox (London) four. Scarlet fever and measles continue to decline, whooping-cough to increase. The death-rates ranged from 19.6 in Sunderland to 35.1 in Plymouth; London 31.3; Bristol 27.6; Birmingham 26.8; Liverpool 30.6; Manchester 27.7; Leeds 27.9. In Edinburgh 24, Glasgow 23, Dublin (small-pox four deaths) 43. In the 20 chief towns of Switzerland, with an estimated population of 445,790, there were 225 deaths reported and 269 births, with a remarkable exemption from infectious diseases: acute diseases of the respiratory organs caused 44 deaths; diarrhoea seven, diphtheria and croup four, whooping-cough one, erysipelas one, fever one. The total death-rate was 26.3; Geneva 23.2; Zürich, 24.4; Basle 19.6; Berne 36.2; Lausanne 29.6.

The meteorological record for the week in Boston was as follows:—

OBITUARY: DR. JOHN CLOUGH.

In the progress of human events and the dispensations of an all-wise Providence, the Middlesex East District Medical Society mourn the loss of an esteemed fellow in the death of Dr. John Clough, of Woburn. Dr. Clough was born in Gilmanton, N. H., January 23, 1809. In 1836, he began the study of medicine at Dartmouth College, where he graduated with credit in 1839. He shortly after began general practice in New Ipswich, N. H. Two years later he removed to Woburn, Mass., where he enjoyed professional success until 1844, when he abandoned medicine and learned dentistry, in the practice of which art he became very proficient and eminently successful in Boston and Woburn until near the close of his life, which occurred at his home in Woburn, November 25, 1879. Dr. Clough was one of the original members of this society, and the last resident survivor (with one exception) of those physicians who participated in its formation. In the death of Dr. Clough this society has lost a true and honest friend. While we therefore mourn his loss, we also place on record our hearty appreciation of his excellent qualities of mind and heart. We shall always recall with pleasure his frank and noble character, his fearless expressions of his own convictions, his honesty and uprightness, his catholic charity and sympathy with the down-trodden and oppressed, his active interest in medicine and sanitary science, and his cordial hospitality towards his professional brethren. To the bereaved family we acknowledge our heart felt participation in their sorrow.

F. F. BROWN, President.

GEO. E. PUTNEY, Secretary.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JANUARY 17, 1880, TO JANUARY 23, 1880.

TAYLOR, M. K., captain and assistant surgeon. The leave of absence granted him from head-quarters, Department of Texas, is extended one month. S. O. 9, Military Division of the Missouri, January 19, 1880.

WORTHINGTON, J. C., first lieutenant and assistant surgeon. Relieved from duty at Fort Grant, Arizona Territory, and assigned to duty at Fort McDowell, Arizona Territory. S. O. 4, Department of Arizona, January 8, 1880.

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next regular meeting of the society will be held at the Medical Library Rooms, 19 Boylston Place, on the first Thursday of February, at seven o'clock, P. M. Profession invited.

HENRY M. FIELD, M. D., Secretary.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting will be held Monday evening next, at eight o'clock, at 19 Boylston Place. Reader, Dr. Chadwick. Subject, The Hot Rectal Douche.

FREDERICK C. SHATTUCK, M. D., Secretary.

SUFFOLK DISTRICT MEDICAL SOCIETY. — A regular meeting will be held at the hall, No. 19 Boylston Place, on Saturday evening, January 31st, at seven and a half o'clock. The following papers will be read: Dr. E. Cheney, The Evil Effects of Alcohol on Offspring; Dr. Walter Channing, Restraint in the Treatment of Insanity. Supper at nine o'clock.

T. M. ROTCH, Secretary.

BOOKS AND PAMPHLETS RECEIVED. — Valedictory Address to the Graduating Class of the Medical Department of the University of California. By W. F. McNutt, M. D., L. R. C. P., Ed., etc. (Reprint.)

Transactions of the Medical Association of the State of Missouri at its Twenty-Second Annual Session. St. Louis. 1879.

Experimental Researches on the Regional Temperature of the Head under Conditions of Rest, Intellectual Activity, and Emotions. By J. S. Lombard, M. D., formerly Assistant Professor of Physiology in Harvard University. London: H. K. Lewis, 136 Gower Street. 1879.

Lectures.

CLINICAL LECTURES ON THE PHYSIOLOGICAL PATHOLOGY OF SYPHILIS.

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK, SESSION OF 1878-79.

BY FESSENDEN S. OTIS, M. D.,

Clinical Professor of Genito-Urinary Diseases, etc.

LECTURE V.

PERIOD OF LYMPHATIC OBSTRUCTION.

GENTLEMEN, — We have now followed the natural history of syphilis, in its clinical, physiological, and pathological aspects, from its assumed initiation (by contact of a degenerate amœboid corpuscle, or disease germ, with the healthy human white blood corpuscle), into and through the lymph spaces and channels; from the point of original contact, or inoculation, to and into the general blood current. From thence we have also traced its course through most of the manifestations characteristic of the active period of syphilis.

We have seen that wherever the syphilitic influence was recognized, the underlying conditions, culminating in a syphilitic manifestation, were in every instance attributable only to excessive localized cell proliferation and accumulation; and, further, that this local proliferation and accumulation were favored by certain anatomical conditions in localities long recognized, clinically, as the favorite seat of such manifestations.

The active period of syphilis, thus shown to be marked by excessive localized cell proliferation, was shown to be equally characterized by the contagious property attaching to cells thus generated. Inoculation of the blood and of the secretion of all open lesions during the active period of syphilis has been found capable of communicating syphilis promptly to healthy persons.

The physiological secretions — that is, milk, saliva, urine, perspiration, tears, and spermatozoa — have not been proven to be agents of syphilitic infection. Where apparently so, in many cases syphilitic lesions of the mouth or breast have been found to account for the seeming inoculability of the saliva or of the milk. Repeated experiments¹ have been made by inoculation of the spermatic fluid of a person proven to be in the active stage of syphilis upon healthy persons with absolutely negative results. In this we find confirmation of our position that the contagious property is not an entity, an independent virus, pervading all the tissues and fluids of the organism, but that it is confined to the white blood or tissue-building cells, and in this view we readily see how the physiological secretions above mentioned, which do not contain them, are found also to be free from the contagious property of syphilis.

Thus far the *only distinguishing feature* which has been recognized between normal embryonal cells and cells which make up the accumulations characteristic of the active stage of syphilis is the possession by the latter of the *contagious property*; in other words, a *contagium*, — the power of setting up in other cells, through simple contact, the same disposition to rapid proliferation which the so-called syphilitic cells are known to possess. The direct result of this hasty pro-

liferation, as far as we have yet been able to discover, is *not a destructive action*. It is simply and only what we should naturally expect from hastily generated normal material in excess of the necessities of growth and repair. In representative, uncomplicated cases it remains for a time obstructing the tissues by its presence, and then through purely normal processes, often of necessity set into operation by crowding of the newly-formed cells, prolonged pressure, and consequent innutrition, and also from general causes, it undergoes fatty degeneration, and is in this way finally eliminated from the affected organism.

Bäumler virtually supports this view² when he says of the active stage of syphilis, "If there are only a few local deposits the elimination of the virus may be so much in excess of its production that the organism is gradually freed from it. *This takes place in the majority of cases, and at the expiration of eighteen months or two years the infection is entirely exhausted.*"

Mr. Hutchinson, of London, in speaking of the contagious property which attaches to the emulsified white blood cell which we call pus, says, "*All living pus is contagious.*" . . . I mean," he further says, "that all pus cells possess the power of setting up, when transferred to another home, if that home be a suitable one, a kind of inflammatory action similar to that from whence they themselves had originated."³ This we know results in the almost immediate death of cells in localities so contaminated. In the case of the germinal cells contaminated by contact with the syphilitic cells, however, this results only in an imperfection, which prevents their highest development; they fall by the way, are heaped up, undergo fatty degeneration, and are, or may be, eliminated. Nor is it alone in diseased cells that a contagious property is claimed to reside. Rindfleisch, an eminent German authority, in speaking of embryonal cells coming up from the tissue juices for the regeneration of mucous membranes, says of such cells that "*they become epithelial cells only by coming into contact with such.*" We must believe," he continues, "in a kind of epithelial infection. This," he says also, "must of course just as well obtain when embryonal formative cells approach an existing epithelial stratum as when, conversely, epithelial elements approach embryonal formative cells."⁴ If this be true, it at once becomes evident that the contagious property is not of necessity a virus. Is it not then possible that the mischief which syphilis does is rather the result of an interference with the normal processes through hasty development than of the action of a specific virus?

In any event, this contagious property of syphilis *ceases with the active period of the disease*. After this has passed, the secretions of open lesions and the blood no longer contaminate. It may also be said that in by far the greater number of subjects of syphilis (and more especially those who have been systematically and judiciously treated) they remain free from any further sign of the disease. If this be so, then we may legitimately claim that at the termination of the active period of syphilis, just described, all subsequent troubles must be looked upon as sequelæ, and not as a stage of syphilis, any more than we should look upon dropsy as a stage of scarlet fever or stricture as a stage of gonorrhœa. Mr. Hutchinson, who is recognized as one of

³ *Text-Book of Pathological Histology*, Rindfleisch, Am. ed., 1871, page 100, § 83.

⁴ Dr. Mireur, of Marseilles, *Annales de Dermatologie et de Syphilographie*, No. 6, Tome viii., 1877.

the most advanced of the English authorities on syphilis, says, "*What are called tertiary symptoms do not constitute a necessary stage, and are rather to be regarded in the light of sequelæ, which may or may not show themselves.*"¹ Mr. Henry Lee (also a valued authority), in his Hunterian lectures delivered at the Royal College of Surgeons of England in 1875, presents the same view of so-called tertiary or late syphilis thus: "*The pathological changes in this class occasionally, according to Mr. Lane's view, present themselves in patients who have passed through the primary and secondary stages of syphilis, but in whom the venereal poison no longer exists, and therefore cannot be transmitted.*"

This is, I know, quite at variance with the usual teaching in this matter. The accidents following upon the active period of syphilis are usually represented, not as sequelæ, but as the direct result of the syphilitic virus, which had never been completely eliminated, but is said to be still present in a latent state. Authorities are quite agreed, however, in regard to the clinical fact that after a varying interval of from one to forty or fifty years from the acquirement of syphilis a new variety of lesions appear in certain cases—sometimes within a few months—in the form of an eruption on the skin similar to the one I now present to you.

CASE IX. This young man gives us the history of a sore on his penis fully three years since, coming on three or four weeks after a suspicious connection. This was followed in a few weeks by an eruption which his medical adviser told him was syphilitic; he also had sores in his mouth and throat, all of which disappeared after a mercurial course of a month or so. He had supposed himself entirely well when, about a month ago, another eruption appeared on various parts of his body.

We are here at once struck with the deep wine color of a patch of papular elevations on the temporal region, irregular in form and extending somewhat upon the forehead. A casual observer might perhaps confound it with the papular eruption of syphilis, which has been so often before us. But you will, by a moment's inspection, find well-marked and important differences. First as to color: here we see a distinct purple hue, instead of the ham color of the papular syphilide. In the next place, instead of being symmetrically distributed, the eruption occurs in patches; here is quite a large one, the size of my palm, on the right scapula; another on the thigh. There is an indication that the cause of this trouble (unlike the papular syphilide) has not been free in the blood. Again, the induration is also deeper, involving the whole thickness of the skin. Here, also, on the scapula, will be seen a number of small cicatricial depressions, where resolution of the eruption has taken place, evidently *without ulceration*. I may here state that this is the usual course in this, the *tubercular eruption* of so-called *tertiary syphilis*.

CASE X. Here I show you another example, where the tubercles are much larger, only half a dozen in number, and are confined to the right side of the nose. In this case active syphilis occurred four years ago, and the present lesion appeared as small red elevations of the skin about two months since.

In this lesion you see even more distinctly than in the other case the loss of tissue which has occurred, the site of which is marked by several small cicatrices.

A large tubercle is here covered by a scab; on removing this we find only a superficial excoriation. Loss of tissue in these cases does not commonly result from ulceration, but from absorption of a material which has been infiltrated into the tissue. The scars here give the lesion the appearance of simple tubercular lupus, and mistakes of diagnosis on this account are very common. We find in the excellent work of Van Buren and Keyes an explanation of the manner in which *scarring without ulceration* occurs in these cases, thus: "The syphilitic tubercle is due to a diffuse hyperplasia of small cells in the substance of the true skin. These cells, which partake of the nature of the so-called *gummy* exudation, grow at the expense of the natural tissues, and cause the atrophy of more or less of the substance of the latter, even while there is apparently a hypertrophy, as evidenced by the little tumor called a tubercle. When, however, the adventitious newly formed cells go into atrophy and are absorbed, during the progress of the eruption, then not only does the tubercular prominence disappear, but the scar left attests the atrophy and absorption of the true elements of skin tissue which took place during the deposit of the morbid material."²

In the opening of this analysis of the syphilitic tubercle, it is said to be "due to a diffuse hyperplasia of small cells in the substance of the true skin;" at the close, it is characterized as a "deposit of the morbid material." A little further on I propose to bring evidence to show that this lesion, in common with all syphilitic sequelæ, is not due to a hyperplasia, such as we recognize in the papular syphilide and in all the new formations of the active stage of syphilis, but that it is due to a *deposit*, not of *morbid*, but of *arrested normal material*.

CASE XI. Again, here is an old man, sixty-five years of age. He has come to our clinic on account of an enlarged testicle. His attention, he states, was drawn to it about three months since, first by a sense of heaviness in the organ. He then noticed that it was double the usual size. Since that time it has progressed, without pain or any especial annoyance except the dragging sensation, to the present size. The right testicle now presents to us as an ovoid tumor, fully four inches in its vertical diameter and three in its horizontal as the patient stands before you. To the touch it is hard, not sensitive. A small amount of fluid is present in the tunica vaginalis, but not enough to obscure the somewhat irregular outline of the tumor. There is no history of any urethral discharge, or injury to the urethra, or prostate, or testicle, but there is a pretty clear history of an occurrence of syphilis at the age of twenty-four, and thus *over forty years ago*, a sore on the penis coming at a long time after connection; he cannot remember exactly, but estimates it at from three to four weeks. He took mercury for a while, until it healed, and no further trouble was noticed. He married a few years after, and has had several children,—four,—also grandchildren, not one of whom has had any recognized signs of hereditary taint. Notwithstanding this I do not hesitate to suspect that the difficulty of the testicle will prove to be a sequel of syphilis. The physical signs accord with such a view; the history is sufficiently complete to warrant such a conclusion (many persons pass through the active stage of syphilis without its recognition by themselves or others). The final test here will

¹ London Lancet, page 88, January 17, 1874.

² Genito-Urinary Diseases with Syphilis, Van Buren and Keyes, page 583, New York, 1874.

be the effect of treatment which we find so promptly curative in such cases as to be of great diagnostic value, namely, that by mercury and the iodide of potassium. This is another of the so-called tertiary manifestations of syphilis.

Do you ask me, Of what is this enlargement and induration made up? I answer in accordance with the usual teaching, Of "gummos material." — the same that is found in the tubercular eruption in Cases IX. and X.

CASE XII. Again I present you a form of trouble which has followed an attack of syphilis after a very long interval of apparent good health. Fifteen years ago this man (who is now fifty), according to his very clear and intelligent statement, had unmistakable syphilis, and characteristic initial lesion, early erythema, general papular eruption, mucous patches, etc. After several months among quacks, he was finally treated by a well-known surgeon of this city for about a year; then, being apparently well, he left off treatment. About six months ago, or some fourteen years from the date of initial lesion, and after some months of dissipation, he began to suffer with a catarrhal trouble which became fetid. It was not, however, until a characteristic perforation of the hard palate had occurred that the source of his trouble was suspected, and he then went up to Charity Hospital for treatment. Here, as you can observe, is a distinct loss of structure involving a portion both of the hard and the soft palate. Repair is going on in the soft parts under appropriate treatment, which I wish to remind you is the same which has been prescribed for the three cases preceding, namely, mercury and the iodide of potassium. Why? Simply because the source of the trouble has been shown in such cases to be dependent upon the gummos deposit in the soft palate and in the bony arch of the mouth and in the vomer, which also he has evidently lost.

CASE XIII. The patient is a man of forty, who presents several ulcers of the legs which we term characteristic of so-called tertiary syphilis. They are abrupt losses of integument as if some foreign substance had sloughed out; bluish thickened edge, undermined, and on pressure giving exit, not to pus, but to a thin, serous fluid. Here are also two or three points, higher up on the calf, slightly elevated, and to the touch giving a distinct sense of fluctuation. The physical appearances here are alone sufficient, even without a history of antecedent syphilis, to warrant the diagnosis of gummy tumors; although the patient claims to have had syphilis ten years since. I introduce a history into one of the seemingly fluctuating points, and not pus, but a serous fluid, exudes. Both the secretions and the tumor will be found to consist of the same material which we recognized as constituting the tubercular eruption in Case IX., which caused the induration and enlargement of the testicle in Case X., which also caused the destruction of the soft palate and bony structures in Case XI.; and this has been proven, by repeated and exhaustive microscopical examinations, to be made up of gelatinous fluid containing normal cells and nuclei which do not differ in the least demonstrable degree from the white blood cells and nuclei of a healthy person. Wagner, perhaps the most recent standard authority, says in 1876 of this material, which he terms *syphiloma*, "Microscopically, syphiloma consists of cells, or nuclei, or both at the same time, so that sometimes the former, sometimes the latter, exceed in number. Young syphilomata, as well as the peripheral parts of the older ones, contain for

the most part only nuclei, or nuclei and isolated cells; the older syphilomata, not yet very atrophic, consists for the most part only of cells, or of cells with few nuclei. *The nuclei offer nothing characteristic.* They are from 0.01 to 0.02 mm., large, round or rounded, or somewhat angular, and contain for the most part a distinct nucleolus. *The cells resemble most uninnucleate colorless blood corpuscles*; their size varies, however, sometimes between 0.01 and 0.03 mm.; some are even still larger."¹ Again Wagner (page 436) says, "The influence of syphiloma on the organism depends upon the fact that the affected portions of the membrane and parenchymata are more or less incapable of function; partly on the deposit of cells, and especially of nuclei, upon compression or secondary atrophy of the gland cells, nerve fibres, ganglion cells, etc."

Bäumler, who fully adopts Wagner's views, says, "From the fact of the close resemblance of the cells which pervade the tissues, or occur in the form of young tissue growths, with the white blood corpuscles, it is evident that, however much they [authors] may characterize syphilitic new formations, they *wholly lack specific microscopic characters.*" He also says, "Tumors of this sort [gummy], varying in consistency, may develop in any organ in consequence of syphilis, but their favorite seats are in the subcutaneous cellular tissue, the skin, in and upon the bones, the liver, the testicles, the brain, the kidneys, and, especially in children, the lungs. According to Wagner's description," he further says, "they present the appearance of a grayish-red, soft, homogeneous mass, either without fluid contents, or else yielding a scanty juice like mucus. They may occur as infiltrations of microscopic size scattered throughout the parenchyma of an organ; and even when they appear as sizable tumors, as large as a walnut or larger, they are not encysted nor sharply defined, but merge directly into the surrounding tissue." "The effects of a gummy tumor," says Bäumler, "may extend to a great distance in case it has caused contraction of the calibre of some vessel, especially of a blood-vessel, which is particularly liable to occur when the tumor has its seat in the adventitia of a vessel. *Fatty degeneration and wide-spread processes of softening may be the consequences of a tumor in itself insignificant, as occasionally happens in the brain.* When situated in the skin, in the subcutaneous cellular tissue, upon mucous membranes and superficial bones, the gumma often makes its way to the surface, since in these situations it is not uniformly inclosed on all sides, but is exposed to unequal pressure. The entire infiltration then ulcerates." It would then appear probable from the foregoing views that contraction of vessels often plays an important part in causing the lesions of so-called tertiary syphilis, a purely mechanical matter quite independent of the influence of any virus. In passing I desire also to call your attention to the statement that "gumma often makes its way to the surface," as I hope to be able subsequently to show how this occurs, not making its way, but progressing in line of the natural physiological channels. Ricord claims that tertiary lesions are not inoculable, and cannot be transmitted by hereditary descent. Bumstead states in his last edition, after reviewing the matter, "Hence we consider the blood and the secretions in tertiary syphilis innocuous."² "Diday performed inoculations with

¹ Wagner's Manual of General Pathology, Am. ed., 1876, page 435.

² Venereal Diseases, Bumstead and Taylor, page 443.

the blood of persons in the tertiary stage of syphilis, and invariably with a negative result. Von Barrensprung states that from observation as well as experiment he is persuaded that so soon as the syphilis has passed into the destructive forms of its tertiary stage *it ceases to generate an inoculable virus*," and, says Bäumler, "clinical observation seems to confirm this view, both in respect to direct contagion and with reference to the inheritance of the disease."¹

These authorities, together with Lee, Hutchinson, Lancereaux, and many others of our best clinical and scientific observers thus agree fully on this very important point. What, then, is there to show that the so-called "*period of gummy products*" (Lancereaux) is not simply a period of possible, but not necessary sequele when it is found practically by competent observers to be free from the contagious property, and when by scientific investigators it is shown capable of producing all the lesions, without exception, which ever occur in the so-called tertiary or gummy stage of syphilis?—and this by interference with function, not improbably through pressure, occasioned by the presence of abnormal or excessive accumulations of material, which the most experienced and learned microscopists can not distinguish from the normal elements of new formations.

If, then, we accept the lesions of the so-called tertiary stage (or the period of gummy products of Lancereaux) as sequele, where shall we look for the *causes* of the possible accumulations of normal germinal material at every point in the human organism? Naturally, it appears to me, *in interferences with the lymphatic circulation*, the natural channels through which, according to Rindfleisch, the nutritive material exuded into the tissues in excess of the necessities of growth and repair is returned to the general circulation.² Again, according to the same distinguished authority,³ "*Luxurious new formations, catarrhs, and surface secretions of all kinds must be produced when the lymph conveyance is hindered, and*" he further says, "*we will find this position in pathology very frequently confirmed.*" One thing is now admitted by all recent accepted authorities, namely, that all the surface secretions and new formations of the tertiary or gummy period, all the infiltrations and tumors, all the peccant elements which produce the varied lesions in the skin, in the cellular tissue, in the bones, in the viscera, by whatever name characterized, are but the result of various forms of infiltration or deposit of gummy material; and if this is, as it would appear by the results of scientific investigation to be, *nothing more nor less than nominal germinal elements* thus retained at various points, then the only legitimate way of accounting for this retention would appear to be through obstructions, *hindrances to the lymph conveyance*, which Rindfleisch insists is of itself sufficient, independently of any question of syphilis, to produce just such results as are known to occur in the so-called tertiary stage or period of gummy products.

And yet another circumstance would favor this view, namely, clinical experience has shown conclusively that whatever the form or locality or name of a lesion, whether in the skin, as a scaling eruption, or as a tubercular eruption, or as a heaping up of gummy exudation in scabs, with or without ulceration, or as

an ulcerative loss of tissue, or whether as a gummy tumor in the cellular tissue, in the bones, in the viscera, or in the brain and nervous system, one and the same treatment is adopted and found most efficacious and judicious for all, namely, the *administration of mercury and the iodide of potassium*. I have not heretofore objected to the term gummy period, so called only from the similarity of its products to the viscid material which it was believed to resemble, nor to the term *tertiary*, which is a purely arbitrary one. But it appears to me that we may now venture to substitute for these the terms, the *period of lymphatic obstruction*, as more scientific, because expressing the localization of lymphatic elements, which is proven to occur, and as suggesting the lymphatic canal system as among the possible causes of that localization. It appears to me that inasmuch as it has been shown that the lymphatic spaces and vessels are primarily and chiefly affected and obstructed during the active stage of syphilis, it is not unreasonable to infer that damage might have occurred to those spaces and vessels during that active period of syphilis, which, if properly investigated, would lead to the true explanation of the failure of that system to return to the general circulation the germinal material, exuded or developed in the tissues in excess of the necessities of growth and repair, such as is practically demonstrated to have occurred in the so-called tertiary or gummy period of syphilis. There are various known facts and analogies which afford strong presumptive and circumstantial evidence that this view is the correct one. Among these we have, first, the fact, generally recognized, that the more severe and prolonged the secondary or active stage of syphilis the more certain and severe are the so-called tertiary or gummy manifestations. (Hutchinson.) Second, the results of treatment show that the difficulty is not simply an aggregation of infiltration or material, which, when removed, restores the patient permanently, but that the conditions for its reproduction remain, and relapses occur.

Thus the iodide of potassium is recognized as capable of most rapidly removing the gummy material, and thus of relieving symptoms; but mercury is found requisite to produce permanent immunity. The iodide of potassium acts readily in removing recent new formations and cell accumulations, probably through the iodine it contains. The *fiens vesiculosis*, a remedy in use for obesity, and popularly known as "anti-fat," owes its virtues to the same ingredient. But mercury is known not only to hasten dissolution and elimination of fatty matters and new formations; it is, besides, the only agent with which we can expect to disintegrate more or less long-standing fibrous obstructions.

In the gummy accumulations of so-called tertiary syphilis we are obliged to infer that *some* condition remains, after the removal of the peccant material, which predisposes to or causes subsequent reaccumulation. What is more likely, as such condition, than *obstruction of lymphatic vessels*, the office of which is to carry just such material as we find producing the difficulty; vessels, too, that have been, more than any other structures, involved in recognized troubles during the active stage of the disease? More or less inflammatory action, usually of a very low grade, is recognized at different superficial points in the lymphatic system during this period. The well-known tendency of all such action is to the deposit of fibrous material, — the very material of which cicatricial contractions of other tis-

³ Ibid., page 93.

sues are brought about. Analogous in a degree are the conditions which result in stricture of the urethral canal, ten, twenty, or even forty years after the original inflammation,—conditions which set in motion a process which culminates, finally, in obstruction to the passage of urine.

It has been claimed that much of the trouble in so-called tertiary syphilis may be the result of wide-spread fatty degeneration caused by contractions of vessels.

It is well known that fatty metamorphosis occurs more easily in some subjects than in others,—that purulent degeneration is most readily set up in the debilitated and diseased. It is also claimed by high authority that the liability to and severity of the lesions of the so-called tertiary period of syphilis "is in proportion to the duration of the secondary stage." (Hutchinson.)

Thus we may conclude that the varied degrees and forms of so-called tertiary manifestations depend upon, first, the damage caused during the "duration of the secondary stage," and inferentially in consequence of it; and, secondly, upon the condition of the individual affected, and this quite independently of any specific virus.

It may be objected to this view of lymphatic obstruction as a cause of the sequelæ of syphilis that, while all the known physiological and pathological processes favor it, it lacks actual demonstration.

It is unfortunately true that the investigation of these matters requires an amount of special training, knowledge, and experience with the use of the microscope, which puts it practically beyond the province of the general physician or surgeon, and also that experts have paid no systematic attention to the pathological processes associated with syphilitic sequelæ, but have rather wasted their labors in the vain endeavor to find a specific virus to which all these pathological conditions could be directly attributed,—a sort of philosopher's stone, which when found would suggest an antidote with properties as marvelous as those attributed to the virus, and of universal application for cure of every form and result of syphilis. But a single case has rewarded my search in the literature of microscopic investigations of syphilitic lesions which, presented simply as a record of pathological appearances, independently of any theory, appears to confirm my views in regard to the presence and importance of obstructions of the lymph channels in the sequelæ of syphilis.

TERTIARY SYPHILITIC ULCERATION OF THE ILEUM.¹

F., fifty-one years old (counselor), had been healthy, with the exception of syphilis, until six months before his entrance into the hospital. At about that time he felt a weakness in the lower extremities, especially the right, and fatigue in walking. The appearance of locomotor ataxia developed more and more, and this caused him to go into the hospital. At his entrance he was found to be robust, well nourished, with scars of mucous patches on the lips, psoriasis palmaris, and in the right groin scars from ulcerations of the glands.

The digestion was pretty good, stools not bad, no pains in the intestines. On the whole, the case appeared like one of locomotor ataxia.

The treatment against the syphilis was decided, and iodide of potassium and Zittmann's decoction were

prescribed; but the patient was scarcely put upon this treatment when he suddenly died. The post-mortem examination showed the following condition of the intestines: "All the layers of the intestines, from the lower part of the jejunum up to the ileo-cæcal valve, corresponding to Peyer's plates, were pervaded by a gray, reddish mass, which had on these parts a parchment-like feeling; the folds of mucous membrane were broader than normal, stiff, not expansible. In the middle of this infiltration an ulcer was found, of polygonal shape, and of the size of a small silver three-cent piece (kreutzer), parallel to the longitudinal axis of the intestine. The base of this ulcer is formed of the thickened, smooth, fatty-looking submucous layer, the borders of which are flat but sharply marked. The peritonæum is here covered with a tender pseudo-membrane and pervaded by enlarged lymphatic vessels, filled with thick yellowish-white lymph.

"Between the vessels were to be seen numerous little knots, of different sizes, which were in communication with the lymph vessels. The lymphatic glands of the mesentery were slightly rough and swollen. In the cavity of the intestine were bile-colored pulpy feces."

MICROSCOPIC APPEARANCES.

"We found a very abundant growth of round, tender cells, which were partly filled with fat; these after the addition of acetic acid showed several granules. The growths embrace the normal mucous membrane, extend through all the layers, especially the submucous connective tissues, and these, as well as the crypts of Lieberkühn, well preserved, were filled with detached epithelium.

On the ulcer found in the centre of the infiltration the intestinal villi were very imperfect or missing entirely.

"On the smooth, fatty base of the ulcer we saw numerous round cells imbedded in the tissues. The same growth of cells was also present in the muscular structure, in which the cells were imbedded between the muscle fibres which separated them.

"On some parts of the preparation (microscopic) aggregations of cells which had separated the muscle fibres had changed to a molecular mass."

"Upon a cross-cutting of the thickened peritonæum, besides enlargements of the thick-walled vessels and round cells, distributed especially around the vessels, we found also heaps of cells which seemed to be surrounded by a firm membrane."

"The cross-cut of such groups of cells were mostly circular, and showed a space filled with round cells of the same size, which space was marked off from its surroundings by a sharp line. These were taken to be sections of lymphatic vessels."

"Upon the longitudinal cut (especially in places where the enlarged lymphatic vessels and the small knots above described could be seen with the naked eye) were seen frequently heaps of cells surrounded by a sharp line. These heaps of cells took in the whole field of the microscope and were in connection with the lymph vessels. We saw both afferent and efferent vessels, filled with the same cells which formed the contents of the little knots visible to the naked eye." Here we have the history of a well-marked example of the so-called tertiary period of syphilis, or the period of gummy products. These products on a post-mortem examination are found distinctly associated with an ulceration in the intestinal canal, characteristic of syphilitic action. Infiltration of

¹ Untersuchungen an dem pathologisch-anatomischen Institute in Krakau. Von Dr. Alfred Biesiadcki, Professor an der K. K. Universität in Krakau. Mit 11 Holzschnitten. Wien, 1872. Page 84. Die Fälle von Enteritis Syphilitica aus dem Archiv für Dermatologie und Syphilis, 1871. Von Dr. Osier.

round cells (gummy products) into the mucous, submucous and muscular tissues, stiffening the structures so as to produce distinct induration, separating the bundles of muscular fibres until they become reduced to the appearance of a molecular mass, practically a necrosis. *Lymph vessels so distended with cells that a knotted appearance indicates the pressure to which they have been subjected*, and reveals the fact that a localized obstruction to the return of lymph through its natural channels, has occurred, — vessels filled almost to bursting with a yellowish fluid lymph, and cells (gummy material?); and why? What has caused this obstruction of lymph channels and evident loss of substance, by interference with the nutrition of the parts? The microscopic examination fell short of an inquiry into the causes of the obstruction. The tissues of the vessels were not subjected to any test or examination to see how the structure of the walls differed from that of normal lymphatic canals. The observer was content to show us that the damage probably resulted from interference with the lymph circulation; for it is evident that if these vessels (whose office is to return to the general circulation the lymphatic elements exuded in excess of the necessities for growth and repair) had been patent, the accumulation could never have occurred. This case carefully and ably investigated, in its gross as well as in its microscopical features, with no possible suspicion attaching which could indicate on the part of the distinguished narrator of the case the endeavor to form or bolster up a theory, has been shown to be a case of lymphatic obstruction, so associated with a lesion of tertiary syphilis (so called) that it will be difficult to resist the conclusion that the characteristic ulceration (lesion) was caused by that obstruction.

With these palpable indications of the manner in which the so-called gummy products have been localized in the present instance, shall we fall back upon the local presence of the traditional *virus* to account for the contractions of the lymph vessels? Shall we not rather claim of the renowned scientists who have already accomplished so much in the philosophical interpretation of general pathological and physiological processes that they shall afford us a reasonable explanation of the gummy material, — a material which is known not to differ in the least degree from normal germinal material, — and a reasonable explanation for the manner of its accumulation in the tissues in so-called tertiary syphilis. In the absence of other cases similar to the one just presented, and with the probabilities that absence is to be accounted for simply by neglect to look for and investigate, this case, presented by a competent and pre-eminently honest observer, must be accepted as representing facts which may be significant as to what occurs in all collections of "gummy material," — facts which are important as possibly affording an explanation of the hitherto mysterious lesions of so-called tertiary syphilis.

It appears to me that a review of the facts and arguments going to show that the lesions of the so-called tertiary period of syphilis are not the results of the local action of a virus, but are caused through damage to lymph channels in the active period of syphilis, which finally results in this contraction, thus causing obstruction to the passage of lymph and cells and accumulation of that material at various points, — these, together with the case cited, I think, warrant me in terming the period above referred to as the *period of lymphatic obstruction*.

PUERPERAL CONVULSIONS.

BY ALEXANDER R. BECKER, M. D., BERKELEY, CALIFORNIA.

WHAT is the cause of puerperal convulsions? The most frequent answer would be "albuminuria," while others would say "uraemia," "anaemia," or "hydraemia." But, in truth, these conditions are only coincident symptoms of the fundamental disturbance. Let us see what that disturbance is.

The epileptiform character of the true puerperal convulsion is so strongly marked as to have drawn the attention and comment of all observers. May we not, then, be guided in our search by observing the pathological conditions pertaining to true epilepsy? It has been proved by Brown-Séquard that an epileptic attack is always preceded by an anæmic condition of the nerve centres, and especially of the medulla oblongata, and he and other experimenters have succeeded in producing epileptiform convulsions by galvanizing the sympathetic, whereby they caused contraction of the arteries and consequent anæmia of the medulla. It is also well known that epileptic attacks are very frequently produced by remote irritation through reflex action.

But from the medulla oblongata there also arises, at least in part, another system of nerves, whose filaments permeate the coats of every artery and vein in the body, and control and regulate the whole blood supply, the vaso-motor system. And it is through this wonderfully delicate and perfect conservator of force, — our safeguard at every turn, — and through the very performance of its duty, that puerperal convulsions are produced. From the moment of conception it is called upon to send an increased and ever-increasing supply of blood to the uterus and to the young life within it. But this it does and *must* do at the expense of other organs.

Over and above this, however, we know that other agencies are at work, — that the stomach performs its functions imperfectly, that the bowels are torpid, that the liver and kidneys are congested; and so it is no wonder that the pregnant woman habitually becomes anæmic, and hydræmic, and albuminuric. (For it must be remembered that the albumen, casts, and even blood are only evidences of congested or inflamed kidneys, and do not present the reactions found in Bright's disease.) But this impoverished blood is all there is to go to that most sensitive of all organs, the brain. Is it strange, then, that a local anæmia of the medulla should be produced sufficient to cause the convulsions in those who have the predisposition? But it may be said that the vaso-motor system also arises, in part, from the spine. True. And when, in the same manner, a sufficient degree of anæmia has been caused in the spinal cord, we find full evidence of the fact in the character of the convulsions and the tendency to opisthotonos.

"Predisposition" is not a term of such scientific exactitude as to be satisfactory. But, for the time, it must content us. Why is it that one child will void ascaries by the half pint, with no further inconvenience than a slight tenesmus and somewhat disturbed sleep, while the presence of a very few of these little tormentors will drive another child into convulsions or into epilepsy? Why does one person pass an active and (hygienically) careless life without a headache, while

another pays for every indiscretion with migraine or tic? We may suppose the difference to arise from a more or less *irritable* condition of the nerve centres, and with good reason. But the demonstration of this fact has not yet been made. And so we know that the great majority of pregnant and parturient women escape without convulsions, but we also know that the delicate and anæmic women, and especially those characterized by a highly wrought and sensitive nervous organization, are more liable to this terrible complication than their more full-blooded and phlegmatic sisters.

We believe, then, that puerperal convulsions are caused, in those so predisposed, by local anæmia of the great nervous centres, which is produced, primarily, by an insufficient supply of blood to those centres on account of the heavy demand from the pelvic organs; and, secondarily, by the impoverished condition of even this insufficient supply. And it will be seen that this theory exactly fits in with the prophylactic treatment now employed by all the best physicians, which consists in relieving the torpor of the bowels, in removing, as far as possible, the congestion of the kidneys; in other words, in removing every local congestion which might help to draw yet more blood from the brain, or become the source of reflex nervous irritation, and in correcting the anæmia with iron, chlorate of potash, etc.

RECENT PROGRESS IN MEDICAL CHEMISTRY.

BY WILLIAM B. HILLS, M. D.

URINARY CHEMISTRY.

The Urine of New-Born Children.—Cruse¹ publishes the following results of his investigations on the urine of new-born children:—

(1.) The absolute quantity of urine for twenty-four hours increases quickly and considerably from the second till the fifth to tenth day; from the tenth to the sixtieth day slowly and inconsiderably.

(2.) The specific gravity and the percentage composition of the urine in its essential constituents diminish quickly till the fifth to tenth day; after the tenth day the diminution is scarcely perceptible. There is an exception, however, in the case of phosphoric acid, which increases with the age.

(3.) The quantity of urine for twenty-four hours, reckoned for one kilo. weight of the body, and of the essential urinary constituents, increases rapidly from the second till the fifth to tenth day, and then remains, with insignificant variations, at the highest point reached till the sixtieth day. There is an exception in the case of sodium chloride, which diminishes again after the tenth day.

(4.) From the fifth to the tenth day the urine is generally cloudy, its color often dark, its reaction frequently acid; after the tenth day the urine is always clear, its color a pale straw yellow, its reaction generally neutral.

(5.) Until the tenth day the urine frequently contains albumen, after the tenth day never.

(6.) In general the urine undergoes many changes from the second till the fifth to tenth day; after the tenth day it is quite constant. The time at which it begins to remain constant corresponds with the be-

ginning of a marked increase in the weight of the child.

(7.) Aside from age, the excretion of urine in new-born children is influenced by the weight of the body. The absolute quantity of urine for twenty-four hours is directly, the quantity per kilo. weight of the body is inversely, proportional to the weight of the body. On the other hand, the absolute quantity of urea and sodium chloride, also the quantity per kilo. weight of the body, is in direct proportion to the weight. The specific gravity also, and (during the first ten days) the quantity of coloring matter, are increased in the same ratio to the weight.

(8.) In comparison with the excretion of urine in adults, the quantity of the urine of new-born children for twenty-four hours, reckoned for each kilo. weight of the body, is about three and one half to four times greater; while the quantity of the essential constituents of the urine, reckoned in the same way, is about one and one half to three and one half times smaller, and of the latter the excretion of urea in children is the least, the excretion of phosphoric acid the most, diminished.

Pollak² has examined the urine of two healthy babies, respectively one and two months of age, for sugar and albumen, and in both cases obtained positive results. These observations are different from those of Cruse, who never found sugar or albumen in the urine of healthy babies after the tenth day.

Cruse,³ in answer, maintains the correctness of his former statements, and attempts to show that Pollak's albumen was only mucin.

Sugar.—Worm Müller and J. Hagen⁴ have compared Fehling's and Knapp's (with mercuric cyanide) methods for the determination of sugar, with reference to their application to the urine, and found that they give, in general, consonant results; only that Knapp's method is more easily and quickly applied, and for this reason deserves the preference. As long as the quantity of sugar was above 0.5 to 0.7 per cent. the indications furnished by the two processes practically did not differ. When, however, the amount of sugar was below 0.7 per cent. it oftentimes could not be determined by Fehling's solution, as the suboxide of copper was held in solution. In such cases Knapp's method was of great value, since by means of it even 0.1 per cent. sugar was easily detected, the mercury settling well. They call attention to the fact, and insist strongly on its recognition, that the figures obtained by either method do not express the amount of sugar alone which is present, but express, in sugar equivalents, the strength of the urine in all reducing substances present (uric acid, for example, reducing both solutions). The authors note the fact that the filtrate from Fehling's test is free from suboxide of copper when the amount of sugar is large, but not when only very small amounts are present, and seek an explanation in the relative quantity of other reducing substances present.

Besides its unlimited application, Knapp's method possesses the advantage of being easily and quickly employed; the end reaction is easily recognized; the mercury separated settles quickly, and does not dissolve again, even on long exposure of the fluid to the air.

² Jahrb. über d. Fort. der Anat. u. Phys., 1878, page 381, from Jahrb. f. Kinderheilk., N. F. 12, 176.

⁴ Jahrb. über d. Fort. der Anat. u. Phys., 1878, page 390, from Arch. f. d. ges. Phys., 16, 567.

¹ Jahrb. über d. Fort. der Anat. u. Phys., 1878, page 380, from Jahrb. f. Kinderheilk., N. F. 11, 393.

Another important question studied was whether urine containing albumen can be titrated directly or only after separation of the albumen, as is usual. When the quantity of albumen was not over 0.2 per cent. they found that it made no essential difference whether the albumen was separated or not. The facility with which the titration was made, however, diminished, the nearer the limit of 0.2 per cent. was reached. Under these conditions much suboxide of copper went into solution, while the mercury settled slowly; but while under these conditions Fehling's method might be altogether impracticable, this was not, properly speaking, the case with Knapp's method, the execution of which was only considerably delayed. The authors conclude, therefore, that it is almost impossible to obtain a better reagent for the titration of sugar than Knapp's.

Indican.—M. Hemmige¹ reports the results of his estimation of the amount of indican in the urine in various diseases. The method employed was that of S-mator.² He found the amount of indican small in chlorosis without complication, increased in a case of pernicious anemia, diminished in two cases of purpura hæmorrhagica, increased in typhus at its height and during convalescence. In intermittent fever it was generally not increased; but in a case with violent cardiac pains and vomiting it was increased during the occurrence of these symptoms. In a case of arsenical poison the amount was diminished, in three cases of lead poisoning and three of trichinosis increased. Further, an increase was found in peritonitis, in gastro-intestinal hæmorrhage, cholera morbus, acute gastro-enteritis, chronic intestinal catarrh, cancer of the stomach and liver, Addison's disease, and progressive muscular atrophy. A normal or diminished quantity was found in constipation, catarrh of the gall-ducts following upon gastro-duodenal catarrh, cirrhosis of the liver, ovarian tumor, acute miliary tuberculosis, hæmorrhage from the lungs, meningeal apoplexy, and cerebral tumor. In phthisis there was a greater quantity when diarrhœa was present than when not.

Phenol.—Phenol, like indol, is a product of the putrefaction of albuminous matters. It has been recognized by Brieger³ as a substance formed by putrid decomposition in the great intestine and the extract of fecal matters. Fifty kilos. of feces furnished 0.2496 grams tribromophenol, corresponding to 0.0708 grams phenol. Phenol is eliminated through the urine in variable proportions in different diseases. The normal quantity eliminated each day by an adult is, according to Munk,⁴ on a purely animal diet 0.006 grams, on a mixed diet 0.0165 grams, reckoned as tribromophenol; according to Brieger,⁵ on a mixed diet 0.013 to 0.099 grams tribromophenol, corresponding to 0.003 to 0.028 grams phenol. Phenol exists in the urine as phenol-sulphuric acid, and may be separated and estimated by mixing with the urine so much concentrated acid as will furnish a five-per-cent. solution, and distilling. The phenol is precipitated in the distillate with bromine water as tribromophenol, and weighed. Each one hundred parts tribromophenol correspond to 28.3 parts phenol.

Experiments made by Oleniatt⁶ on the putrefaction

of different albuminous matters for different periods of time show that the quantity of indol formed increases during the first eight to twelve days, but after this it visibly diminishes, owing probably to its volatility. The phenol formed, however, always increases with the time. These experiments show that the formation of phenol does not run parallel with that of indol, and from this one can conclude that, while an increase of indican in the urine indicates an intense intestinal putrefaction in its first stages, an increased phenol excretion would show that the albumen had remained longer in the intestine and had undergone there putrefaction.

Brieger⁷ has made determinations of the amount of phenol in the urine in different diseases, with the object in view of obtaining a better idea of the putrefactive changes taking place in the intestines. He obtained the smallest quantity in anæmic and cachectic persons in cases of pernicious anemia, acute anæmia after *post-partum* hæmorrhage, chlorosis, scorbutus, scrofula (a case of gland tumors especially in the neck, and amyloid degeneration of spleen and liver), and cancer of the gall-bladder with secondary cancer of liver. The mean in the foregoing cases amounted to 0.0048 grams phenol per day. In diseases of the stomach the separation of phenol was small, but higher than normal in two cases of carcinoma of the stomach. There was about the normal quantity in pulmonary phthisis; a somewhat small amount, at times only traces or even none, in the acute exanthemata; a trace only in two cases of typhus, but the normal quantity in a third case; a marked increase in cholera morbus; a small amount only in perityphlitis; a slight increase in catarrh of the gall-ducts; a large increase in acute peritonitis and traumatic tetanus; and a considerable increase in rheumatic tetanus. In infectious diseases and septic conditions the increase was especially marked. A patient with purulent empyema separated as a maximum 0.6309 grams phenol; the amount diminishing as the patient improved, finally becoming normal. The phenol was also largely increased in a case of puerperal fever with facial erysipelas and exudation of pus, and in a case of phlegmonous abscess. In the latter case the pus itself contained an abundance of phenol. In other serous fluids and exudations neither indol nor phenol was found. Long-continued constipation, whether pathological or induced by opiates, caused only a trifling increase, and that by no means constant. The result of this last observation seems to indicate that one must seek outside the intestinal tract for the cause of the great increase of phenol noticed at times.

Another fact made evident by Brieger's investigations is that the excretion of phenol is not parallel to that of indican. For, although in cancer of the stomach, acute peritonitis, and traumatic tetanus, there was an increase of both, in anæmia and diseases of the stomach there was a diminution of phenol with an increase of indican, while in empyema there is an increase of phenol with a diminution of indican. Salkowski⁸ also states that the excretion of phenol is not parallel with that of indican, but notes the increase of both in peritonitis, pulmonary phthisis and lymphosarcoma. He also finds an increase after ligature of the intestines in dogs and rabbits, and states that a rich diet of albumen appears to increase the amount of phenol sep-

arated. Brieger finds an increased separation of phenol as well as associated sulphuric acid in man after the ingestion of tyrosin, which is derived from albuminous substances.

In connection with the question as to how far one may judge, from the quantity of phenol separated in the urine, of the intensity of the putrefactive processes taking place in the intestine, certain investigations of Schaffer¹ and Tauber² are important. They have found that, after feeding dogs with a weighed amount of phenol, only a portion of the phenol is found again in the urine. When small amounts are given nearly all is oxidized; in case of large amounts (0.12 to 0.48 grams) from 45 to 65 per cent. is oxidized. It is apparently not changed to oxalic acid (as was suggested by Salkowski, who found a small amount of oxalic acid in the blood of a rabbit under similar conditions), since there is no increase of oxalic acid in the urine, but is probably oxidized to carbon dioxide and water. Salkowski³ has also noticed the same fact in regard to the oxidation of phenol. There is therefore no direct relation between phenol separation and phenol formation.

After phenol has been taken (Salkowski, Schaffer), or tyrosin (Brieger), not only is the phenol increased in the urine, but also the associated sulphuric acid; and the quantity of the latter is considerably greater than is necessary to combine with the phenol and indican in the urine. So that the urine must, under these circumstances, have contained some other substance combined with sulphuric acid. The nature of this substance is unknown, but Brieger thinks that a blue coloring matter which adhered to the baric sulphate obtained in the determination of the associated sulphuric acid, and which went into solution on washing the precipitate with alcohol, may have had some connection with the increase of sulphuric acid.

The Urine in Intestinal Catarrh.—J. Fischl⁴ has repeatedly found casts in the urine both in severe forms of intestinal catarrh and in the mild forms, especially in old persons. These were for the most part small hyaline casts, dotted here and there with epithelium, pus, or fragments of these. The epithelium was from various parts of the urinary tract, and at times, even from the beginning, was in a state of fatty degeneration. Blood globules were rarely found, and then in very small numbers. The urine generally contained more or less albumen, while the quantity of urine appeared to be diminished. These appearances were generally observed within a few hours after the diarrhoea set in, and disappeared after a few days, without leaving any trouble.

In young persons and those of middle age these changes in the urine were only found when at the same time vomiting existed. Fischl is inclined to seek for the cause of these changes in the urine in the supposed diminished arterial pressure following upon collapse; just as, though in a higher degree, disturbances of the circulation in cholera are the cause of the changes in the urine which occur in that affection.

Kreatinin.—According to Weyl⁵ if one adds to a dilute solution of chloride of kreatinin a few drops of a solution of nitro-prusside of sodium, so dilute as to be scarcely colored, and then drop by drop a very weak

solution of sodic hydrate, the mixture soon assumes a ruby red tint. This color is transient, being replaced after some moments by the straw-yellow color of alkaline solutions of nitro-prussides. Fresh human urine gives this reaction very distinctly, and it is not produced by any other substance found in the urine except kreatinin. In an alcoholic solution the reaction is less obvious.

Bile Pigments.—M. Masset⁶ considers the following the most delicate test for the detection of biliary coloring matters:—

Two grams of urine are acidified in a test tube with two or three drops concentrated sulphuric acid, and a crystal of potassium nitrite is added, care being taken that it does not adhere to the sides of the tube. The reaction takes place immediately, and consists in the production of streaks of a magnificent grass-green color, if the quantity of the principal biliary coloring is considerable. On being shaken the color becomes uniform and takes on a very deep tint, which persists upon boiling, and which may be kept several days without any alteration. The addition of water simply diminishes the intensity. If the coloring matters are in very minute quantity, the liquid acquires, after a very short time, a pale green tint, equally persistent, and easily observed on placing the tube between the eye and the sunlight, or on looking down the tube as it stands on a white ground. Normal urine under these circumstances assumes a faint ruby tint. Masset considers this reaction valuable in the beginning of certain diseases, when the ordinary reagents are incapable of showing traces; the reaction is always distinct, and is not subject to the errors of observation which may occur with the ordinary reagents and which often lead to indecisive and perhaps erroneous opinions.

TOXICOLOGY.

Localization of Arsenic.—The investigations of M. Scolosuboff upon the localization of arsenic in the organs, from which he concludes that it condenses first and foremost in the brain, have been previously noticed.⁷ Experiments have recently been made by MM. de Poncey and Livon,⁸ which have resulted in confirming the observations of Scolosuboff. MM. de Poncey and Livon have also observed that when small doses of arsenious acid are given to an animal daily with the food the phosphoric acid in the urine is considerably increased. The authors consider that this increase could have come from substitution only, and not from any pathological condition of the animal; for in cerebral affections they have found rather a diminution than an increase of phosphoric acid in the urine. The arsenic then seems to replace the phosphorus of the phosphoglyceric acid, producing arsenio-glyceric acid. The authors are attempting to isolate this base. The experiments are described in detail, and show care in their performance.

E. Ludwig,⁹ however, has made analyses of the organs of persons who had committed suicide with arsenic, and of dogs which had died, some from acute, others from chronic, arsenical poisoning, and in all cases he has found the greatest quantity of arsenic collected in the liver. In acute poisoning the kidneys also were rich in arsenic, while the bones and brain con-

⁹ Chem. Centralblatt, 1879, No. 48, page 602.

tained only very small quantities. In cases of chronic arsenical poisoning (in dogs) which were not fatal, and in which the administration of the poison was stopped, he found that the poison remained longest in the liver, while it was separated from the other organs much earlier.

In a fatal case of acute arsenical poisoning the following results were obtained upon analysis:—

1480 grams liver,	0.1315 grams ammonio-magnesium arseniate.
1481 " brain,	0.0015 " " " "
144 " kidney,	0.0195 " " " "
600 " muscle,	0.002 " " " "
The bones furnished traces.	

[These results are in direct opposition to those of Scodosiuff, De Poncey, and Livon. They are, however, in our opinion of great value, in connection with this question. In every case of acute arsenical poisoning, in our own experience, where the brain has been examined (three in number), and in two other cases of which we have knowledge, only *traces* of arsenic have been found in the brain, while the liver has contained from one half to two and one half grains. It is desirable that all analyses which have any bearing upon this subject be published, and that further experiments be made. For the present we do not think one is justified in accepting the statement that arsenic is chiefly localized in the brain and spinal cord. It is important, however, that the chemist examine the brain in all cases of arsenical poisoning, not only because it will be of value in settling the question under discussion, but also because the presence of traces even is of importance in connection with the subject of post-mortem imbibition of arsenic which is often raised in criminal trial.¹—*Rep.*]

Localization of Strychnia.—*MM. Lajoux and Grandval* have presented to the Pharmaceutical Society of Paris an interesting communication concerning this question. According to some authors (*Husemann, Dragendorff*), the chemist in cases of poisoning by strychnia should direct his investigations chiefly to the liver. *Dragendorff* states that he has never succeeded in isolating the alkaloid from the brain, even when the whole organ was operated on. He states that *Gay* has been able to isolate it from some special parts of the nervous system, as the medulla oblongata and pons varolii, and that he himself has been able to discover it in the medulla oblongata. *Lajoux and Grandval* present the results of their analyses of the brain of a person who died from the effects of 2.35 grams *tr. nux vomica*, equivalent to only 0.0035 grams of strychnia. Of this amount about three quarters was administered hypodermically, the remainder by the mouth. Although the quantity was very small, they succeeded in isolating the strychnia from only a fraction of the brain and obtaining its characteristic tests. If these observations prove correct, the chemist should never neglect, in cases of poisoning by strychnia, to examine the brain.

—*Virchow* has received the order of Knight of the Order of the Netherlands Lion. *Donders* holds the Cross of Commander of the same order. — In Munich Professor *Bollinger* has taken *Bull's* place as lecturer upon pathological anatomy for the present winter. — *Czerny* has been made a privy councillor.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

T. M. ROTCH, M. D., SECRETARY.

OCTOBER 25, 1879. Fifty members were present, *Dr. Calvin Ellis*, the president, in the chair. *Dr. C. J. Blake* read the following paper on

CHILDREN'S EARACHE.

The remark, "Only an earache," so often heard, indicates the familiarity with a symptom which receives the less attention because of its very frequency, and because the appreciation of the facts in the case go no farther than the recognition of the symptom alone.

In too many cases the popular comprehension of an earache may be best expressed as—a hole with a pain at the bottom of it; and to still this pain the hole through which it can be reached, the external auditory canal, is made the medium for the instillation of various substances whose principal value for the accomplishment of the desired purpose lies in the fact that they are warm when used.

The list of substances poured and put into the ears of children by lay practitioners for the purpose of relieving an earache would be amusing, if it were not rather exasperating; for, of the substances usually employed, the majority, while giving temporary relief for the reason mentioned, by remaining in the canal so obscure the objective field by discoloring or macerating the lining of the canal and the outer coat of the membrana tympani as to increase the difficulty of making the subsequent diagnosis as to the cause of the pain, and determining the best measures to be taken for its adequate relief.

The pain itself, in its character and location, as giving evidence leading to the determination of its cause, is too valuable a symptom to be merely palliated and put aside. In the majority of cases the consideration of the cause, in view of its possible consequences, is far more important than that of the present pain; not that the pain is insignificant, but that the treatment should be directed to its relief by removing the cause, like a fire which should be quenched rather than smothered.

Among the causes of children's earache, including the reflex pain from carious teeth and the pain resulting from furuncular and diffuse inflammation of the external auditory canal, by far the most frequent in this climate, and during the winter and inclement spring months, is the acute inflammation of the middle ear accompanying and following the common head cold.

The inflammation of the mucous membrane of the nasal passages and naso-pharynx extends up the lining of the Eustachian tube to the still more delicate lining of the tympanic cavity, a membrane exceedingly rich in blood-vessels, receiving its blood supply in part from branches passing along the Eustachian tube.

One of the first results of the inflammation of the lining of the Eustachian tube is the closure of that passage, which serves both as ventilating shaft and as drain to the middle ear. The pressure of the apposite walls of this tube, by interfering in a measure with the return of blood from the lining of the tympanic cavity, favors the engorgement of the blood-vessels in this cavity and the serous exudation into the tympanic cavity, which latter is a marked feature in these cases,

¹ Compare the *JOURNAL*, January 31, 1878, page 136, *Dr. Drape's* report.

² *Journ. de Pharm. et de Chimie*, August, 1879, page 164.

and is nature's first effort at relief. As this process goes on, there is a gradually increasing accumulation and increasing pressure upon the lining of the cavity, and especially upon the sensitive *membrana tympani*, rendered more sensitive by its own share in the inflammatory process and by the intrinsic pressure from the congestion and serous exudation within its own tissues.

The pain which results under these circumstances is often excruciating, and once suffered is not likely to be forgotten. In addition to the constant and less severe pain, which may be stilled in a measure by dry, warm external applications, there are paroxysms of more severe pain recurring at irregular intervals, due probably in part to an increase of the intra-tympanic pressure, relieved at intervals by the escape of a small portion of the fluid into the Eustachian tube.

This view is supported by the fact that as a rule the pain in these cases is less severe in the day-time, when the child is moving, talking, and swallowing, when the movements of the palato-tubal muscles tend to partially open the Eustachian tube, and by the further fact that the pain is usually more severe at night and after an hour or more of sleep, the child often awakening after a sleep of an hour or two with a pain in the ear much more severe than any which has been experienced during the day. The history of many cases of acute purulent inflammation of the middle ear shows that the pain has recurred in this manner several nights in succession before the natural relief has been afforded by a spontaneous perforation of the *membrana tympani* and a copious discharge. A child suffering from this form of middle-ear disease usually has or has had a more or less severe head cold. There are marked febrile symptoms, as a rule, and the occasional sharp cry marking the access of a paroxysm of pain is peculiar. An examination of the ear shows congestion of the inner end of the auditory canal, congestion of the *membrana tympani*, especially about the *manubrium mallei*, or of the whole surface of the *membrana tympani*, according to the duration of the inflammatory process; or there may be, in addition to these appearances, bullæ upon the surface of the *membrana tympani*, generally on the posterior quadrant, filled with limpid serum, sero-sanguinolent fluid, and, rarely, pure blood, — these bullæ being the result of serous or hæmorrhagic exudation beneath the dermoïd coat of the *membrana tympani*. With these conditions the instillation of warm fluids is evidently likely to do no more than give temporary relief. The thing to be done, under the first conditions mentioned, if possible, is, firstly, to open the Eustachian tube and relieve the intra-tympanic pressure by allowing some of the contained fluid to escape from the middle ear through that passage. This is most readily accomplished, especially in children, by the use of the Politzer air douche. This instrument, consisting of a bag syringe with a flexible rubber tube and appropriate nozzle, is usually used by inserting the nozzle in one nostril, closing the nostrils with the finger and thumb of one hand, making the patient swallow, and at the moment of swallowing compressing the bag, held in the other hand, forcibly. The act of swallowing, accompanied by the elevation of the palate and closing of the naso-pharyngeal from the buccal cavity, prevents the air injected from passing down into the throat. The closure of the no-trils prevents its escape at the nose, and the accumulated pressure in the naso-pharyn-

geal space is exerted to dilate the Eustachian tube, this end being further aided by the contraction of the palato-tubal muscles which accompanies the act of swallowing. The escape of the fluid from the middle ear may be further favored by turning the head so that the affected ear is uppermost, thus bringing the fluid-containing cavity directly above the vertically-situated Eustachian tube; or, if both ears are affected, by inclining the head forward.

But a child suffering from pain is not always readily induced to swallow at the word of command, and possibly, from the existing condition of the throat, forcible swallowing may have been already found to be too painful an experience to render the child willing to undertake it as desired. Since the broad rule, "peaceably if we can, forcibly if we must," is so applicable to the treatment of children, if the act of swallowing cannot be induced, let the child place its hand over its mouth and blow, strongly distending the cheeks, thus forcing the palate upward. During the continuance of this pressure, the addition of the pressure by means of the air-bag in the nose, with closed nostrils as before, will often sufficiently accomplish the purpose.

If the child proves intractable, and can be induced neither to swallow nor to blow, it can be made to cry, if it is not already doing so, and, choosing the moment when a strong cry is sending a column of air out of the lungs and elevating the palate, the desired inflation may be effected.

As a Politzer air douche is not always at hand, and as the busy general practitioner cannot be expected to carry about with him "everything except a tackle and fall," some simpler instrument must often answer the purpose for inflation. A common Davidson injection syringe, the in-draw tube doubled up and held in the hand, and the small nozzle inserted in the nose, answers very well; in default of this, a length of rubber tube, through which the surgeon blows, holding one end in his mouth; and in default of this a common clay pipe.

In the early stage of the inflammation this inflation of the middle ear often not only relieves the pain effectually, but stays the progress of the trouble. The parents can be instructed, and can perform the simple operation on any recurrence of the pain.

When, however, the inflammatory process has progressed still further before proper aid is called for, and the later condition above described exists, the simple inflation is less likely to be sufficiently efficacious, and other treatment looking to a relief of the pressure is called for. This may be afforded often by merely pricking the prominent bullæ upon the *membrana tympani*, or, if there is much bulging outward of the *membrana tympani* from the contained fluid in the middle ear, by perforating the *membrana tympani* itself. This should be done only under good illumination, the child's head being firmly held, and may be accomplished by one or more punctures in the most prominent part of the membrane, or preferably in the posterior inferior quadrant, by means of the lance-headed paracentesis needle, or in default of this by means of a long darning-needle held at an angle in a pair of spring forceps. Acupuncture, unless there is pus to be liberated, is usually to be preferred to an incision, since less violence is done to the already inflamed tissues, and a slight and continuous relief of the pressure is preferable to the complete evacuation of the cavity, which, by removing all counter pressure,

favors a more excessive serous exudation, with possibly the breaking down of the tissues and subsequent ulcerative inflammation.

With the escape of a few drops of the contained fluid the pain is usually greatly relieved, and the gradual flow of the fluid may be now favored, and the maceration of the outer coat of the membrana tympani and the dermoid lining of the auditory canal prevented, by the insertion of a wick of absorbent cotton, to be removed and replaced by a dry wick so soon as saturated.

At this stage the ear should not, as a rule, be syringed, but the dry dressing continued until there is no longer a serous discharge, or until the appearance of a purulent discharge shows that the disease has passed into another stage, when syringing and mild astringent instillations may be re-sorted to, and the usual treatment applicable to such cases carried out, the more acute stage with its excessive pain being a thing of the past.

A word of caution should be added in regard to the use of the air-bag. The inflation should not be too forcible, since the object is rather to dilate the Eustachian tube and favor the gentle escape of the fluid than to force air under extreme pressure into the tympanic cavity. To this end, repeated gentle inflations are preferable, to begin with, to the use of more considerable force. After puncture of the membrana tympani the air douche may also, in some cases, be gently used, and, after both the inflation in the symplic and the puncture in the more severe cases, dry warmth may be externally applied. Moist warmth, the poultice applied over the ear, is as a rule in all of these cases to be avoided.

Dr. HUNT says as follows: Dr. Blake's very practical exposition leaves nothing to be added as far as diagnosis and treatment are concerned; but as to the causation of the affection there are many reasons for doubting the important rôle ascribed to an increase of intra-aural pressure from a secretion that is supposed to have resulted from closure of the Eustachian tube. It has become customary to speak of this cause as quite proven: various authors, often evidently led by a loose idea of an analogy between intra-ocular and intra-aural pressure, which is supported by no facts, have described the operation of puncturing the drum membrane as relieving the pressure in the middle ear if but a drop of fluid exudes. It may be well to remember that the closing of the Eustachian tube leaves the vessels of the middle ear subjected to the pressure of the atmosphere for a much longer time than is necessary to produce the most acute earache, as the phenomena usually succeed each other; and that, on the other hand, many cases of chronic disease are known where, after long closure of the tube, no pain and no exudation occur. Taking these facts into account, I have for some time thought that in the earache of children the pain often has its seat in the membrana tympani, and that puncturing the drum membrane relieves the pain by changes which the operation induces in the membrane itself. If we call to mind the anatomical structure of the membrana tympani, its rich supply of vessels and nerves, it is easy to suppose that an incision which drains it may by this means relieve a most intense pain, of which the cause is seated in the membrane alone, and that the minute effect upon the not remarkably sensitive lining of the middle ear has but little to do with the

good result. In other words, the case is analogous to that of the painful little furuncles which affect the cutis of the meatus, and which an incision so rapidly relieves.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

JANUARY 26, 1880. DR. JAMES C. WHITE, permanent chairman, presided.

CONCUSSION OF THE SPINE, SO CALLED.

Dr. R. M. HODGES read a paper on So-Called Concussion of the Spine, the purpose of which was to show that we have no knowledge justifying the proposition that what is popularly called "concussion of the spine" is due to a molecular disarrangement of the substance of the cord by an assumed shake or jar. That vascular disturbances (anæmia, hyperæmia, hemorrhages, spinal apoplexy) followed by meningitis, myelitis, or degenerative changes of the spinal cord are shown by pathological as well as physiological histology, by experimental pathology, and, to a certain extent, by post-mortem examinations to be the true cause of symptoms heretofore commonly designated as "concussion of the spine." That, in spite of hysteria and exaggerated or fraudulent manifestations frequently accompanying cases of so-called "concussion of the spine," the reality, if not the precise character, of any existing spinal lesion can almost always be recognized by objective and demonstrable symptoms. That the prognosis of this class of spinal injuries, in severe as well as slight instances, is far more favorable than is usually supposed. That, as a plea in suits for damages, "concussion of the spine" (so called) does not and is not entitled to have the weight and importance usually attached to it. That erroneous impressions in regard to the severity of this injury, prevalent in this country as well as in England, have been fostered by Mr. Erichsen's book on Concussion and Nervous Shock, which presents an exaggerated picture of its symptoms and consequences, not justified by our present knowledge of the subject.

Dr. Hodges's paper is to be published.

Dr. CHEEVER said that one great difficulty in cases of alleged concussion of the spine in claims for damages was in distinguishing between the subjective and the objective phenomena, what the patient said he felt and suffered, and what the physician could see, observe, and appreciate without the patient's statement. Another difficulty was in conveying to a jury what the physician honestly believed. This arose from the faulty mode of employing medical experts. It was difficult to avoid being biased when called by one or the other party as expert; and then, again, the most honest expression of a scientific opinion by the expert was discounted by the jury, and passed for less than its worth, because the jury expect the expert to be partisan, and allow for it. Experts should be called and paid by the court, and should devote themselves as specialists to certain classes of cases. Since the publication of Mr. Erichsen's book on Railway Injuries, the imaginative patient, who thought his spine affected, could find in it chapters to feed his fancy and to suggest every symptom, and the adroit counsel could find in it a counter-statement to break down in a cross-examination every statement of an expert. Dr.

Cheever believed the spinal cord to be better protected from concussion than the brain. The cord was swung in a water-bed by the *ligamenta dentata*, and surrounded by a firm but flexible case of bones, held by strong ligaments, and capable of yielding to shocks without displacing the vertebrae; whereas the brain was a larger soft substance, inclosed in an unyielding hemisphere of bone. Frequently injury to the cord was claimed to have been caused by blows over the lower part of the spine, where the cord ceased and was replaced by separate nerves in the *cauda equina*.

Rheumatism was frequently mistaken for injury of the spine. Pain in the back, due to lumbago of the erector spinae muscles, and irritable bladder from excess of uric acid in the urine, simulated spinal irritation or inflammation. The aponeuroses and ligaments of the back, both spine and sacrum, were largely made up of fibrous tissue, were thinly covered by skin and cellular tissue, and were easily inflamed by blows and climatic changes, inducing rheumatism.

Of the cases of alleged spinal concussion as the result of injuries which he had seen, Dr. Cheever recalled but two where the objective phenomena were unmistakable. In one there was *paralysis agitans*, where the involuntary contractions of single muscles and fasciculi could not be caused at will for purposes of deception. In the other there was mottling of the skin, caused by minute capillary congestions, and due to true vaso-motor paralysis.

Dr. J. J. PUTNAM said he supposed we should all agree with Dr. Hodges in his belief that the railroads were badly "gouged," but that from the social standpoint it was to be remembered that up to a certain limit the railroad authorities were made more careful thereby to avoid accidents, which is certainly of great importance. Traveling in Europe is safer than it is in this country, and in Prussia, even under the stringent liability laws, passed in 1871, making the companies responsible for accidents arising in connection with all the business of the roads, thirty railroads were fined but about half a million dollars in three years, a sum no greater than that which was paid by one road here in consequence of a single accident (Wolleston).

With regard to the pathological aspect of the question, Dr. Putnam thought that at present the term concussion had no definite scientific meaning, since we have no evidence that simple mechanical agitation is *per se* able to impair or destroy the functional power of nervous centres, though it was possible that such evidence would be discovered. Such injuries as have been alluded to act, so far as we can now tell, indirectly by causing minute hemorrhages into the cord or its membranes, or by exciting local processes in the neighborhood of the latter (Leyden), or by causing changes in the vaso-motor system. Dr. Putnam could not agree with Dr. Hodges that definite lesions such as might eventually cause myelitis would necessarily reveal themselves by definite symptoms in the early stages of the case, and called attention in this connection to the experiments of Duret and others upon concussion of the brain.

Dr. WEBBER said: When called to examine a patient in case of such injury as has been referred to, the physician called on behalf of the defendant, and often the one called by the plaintiff, is an entire stranger, sees the patient only once or twice, and hence his ignorance of the previous health of the pa-

tient renders a correct diagnosis difficult if the patient desires to deceive. A case in point occurs to my mind where I was asked by the defendant to examine a woman. Testimony was introduced showing that she had had the same symptoms, referable to head and back, before the time of the alleged accident. I found considerable uterine disease, which must have been present longer than the time which had elapsed since the accident, sufficient, at least in part, to cause the symptoms. A gynaecologist confirmed this opinion.

As to the presence of symptoms continuously from the time of the accident, I cannot fully agree with the reader that this is always the case, though I should hesitate to refer symptoms to an accident received so long previously as two years; yet a delay of some months is possible. In one case a workman kept at work and professed to have had no inconvenience after an accident for one or two months, yet died from myelitis resulting therefrom.

That the varied symptoms seen after railway injury are many times genuine is proved by the occurrence of a similar train of symptoms where there is no question of damages, as in a patient who, by sitting down violently, was injured so as to suffer for years in the whole of the back and head, with symptoms like those of spinal concussion. The coccyx being very tender, I advised the removal of this, which was not accepted by the patient, yet after years of suffering and inability, after more than a year's treatment by electricity, she so far recovered as to be able to do a day's work as seamstress.

Sometimes, too, cases which seem to be less severe go on to worse, as in the case of a man thrown from his wagon, having pains in back and legs closely resembling those about which plaintiffs in railroad cases complain. There was no question of damages. He has slowly grown worse, and has many of the symptoms of locomotor ataxia.

The occurrence of impotence has sometimes been claimed, and is held in rather light esteem, as a result of spinal concussion. I was consulted by a gentleman, well advanced in life, who had been injured by the upsetting of a carriage some thirty years before, and had been impotent all that time, though previous to the accident he was not thus affected.

Recovery after severe disability does not prove that the complaints were imaginary, as in a case which came under my care three years or more after settlement, where there was paralysis of one leg. The patient recovered power over that leg after a year's treatment, yet certain cerebral symptoms remained.

Notwithstanding many genuine cases, when testifying in a case where there are no objective symptoms I almost always question whether I may not have been too favorable to the patient, whether called by plaintiff or defendant, there is so much exaggeration and so many attempts at deception, and I generally regret that I have not made statements less favorable to the patient rather than the opposite.

Dr. ELLIS spoke as follows: Though much of the error connected with this subject has been exposed in the paper, the difficulty still lies where it did when the term spinal concussion was introduced. It was only a synonym reiterating the general nature of the accident. After eliminating the various affections of the spinal cord which can be recognized by the presence of certain symptoms, there still remains a residuum to which the term spinal concussion is applied. In other

words, having reached the limits of our knowledge, we embody under this head the vague suggestions of our ignorance. Necessity may at times oblige us to do this, and with advantage, as it is a ready method of communication with each other where the symptoms are constant, even if we do not understand their significance. But nothing could be more vague than the ideas conveyed by this term, and it has been used in connection with cases of which nothing was really known, and which have proved to be nothing but frauds. Mistakes are of course liable to be made in judging of the existence of well-established disease, but in this instance they are made in connection with a hypothetical condition; and on such a basis hundreds of thousands of dollars have been taken from individuals and corporations.

We are told that the term is legitimate because it admits of a prognosis, but it is clear that the latter can be attached just as well to a doubtful group of symptoms which have received no special name. The very cases reported show that no sound prognosis can be made, even with the help of the so-called spinal concussion, as conviction for bastardy has followed not long after the award of large damages for impotence, and motion has returned very rapidly to the hopelessly paralyzed limbs after they have been the means of obtaining a comfortable subsistence for their owner.

The term spinal concussion throws no more light upon the nature of the injury than that of colic does upon the cause of abdominal pain. If we *know* the cause of the latter it is our duty to state it in intelligible language. *We do not add to our knowledge by condensing our ignorance into a formula.*

DR. S. CABOT, in reply to Dr. Ellis, said that he thought that this was carrying the matter too far, and that if we are forbidden to use this term we shall have to stop calling anything by a name. A certain injury occurs and certain symptoms follow. When we find this group of symptoms, it is fair to use the term concussion of the spine, as we say concussion of the brain where there is probably often laceration. He would also criticize Dr. Cheever's remarks in regard to blows of the sacrum below the actual site of the cord.

The worst case that he had ever seen was that of a lady who, thirty years ago, fell on the floor in a sitting posture, a child having pulled away her chair. No part of the spine containing the cord was struck, and yet she became insensible and convulsed, and on coming to was blind, deaf, and had no sense of smell. There was here no question of money at stake, and he called this a case of concussion of the spine.

DR. LYMAN asked Dr. Ellis what he would call a case where a child falls out of bed and is faint, pale, and vomits, without showing any discoverable injury.

DR. ELLIS replied that concussion means nothing, and that when you designate such a case as concussion you give no real answer to the question as to what the trouble is, and merely tell the questioner what he knew before, — that the child had been shaken by the fall.

DR. WEBBER said: As to the term spinal concussion, if one rests satisfied with that and thinks he knows all about the case, instead of carefully examining the patient, — and such cases require the most careful examination and cross-questioning, — the name is a snare; but if the physician will eliminate all gross lesions, as hemorrhages and inflammations, lesions of vertebrae and ligament, there remain a large number of cases whose pathology is as yet unknown, and spinal concussion is a

legitimate and convenient term to apply to them until they can be better known and referred to their appropriate class, whether new or old.

DR. T. B. CURTIS could not agree with those who would set aside the term "concussion of the spinal cord" as having no definite significance. It is certainly neither a nosological nor a pathological designation, since it denotes neither a particular disease nor a particular lesion. It is, however, a clinical designation, applying to certain aetiological conditions; and, as such, is appropriately used when an individual has been subjected to an external violence which may have left no physical signs of injury, but which, as we know by experience, involves a liability to the subsequent development of grave secondary affections of the spinal cord, namely, myelitis, meningitis, and sclerosis.

Concussion, then, is an aetiological circumstance, which, like wetting the feet, may or may not be followed by acute or chronic, curable or incurable, disease of the spinal cord. The symptoms then to be observed are mainly the well-known and unequivocal symptoms of myelitis, followed by ascending and descending sclerosis. Of these symptoms, some, as the disturbances of mobility and sensibility, are subjective, and therefore capable of exaggeration or simulation; others, consisting principally of trophic disturbances, are objective. It is obvious that in cases of litigation, where the pecuniary interests of the patient as plaintiff come into play, the objective symptoms should receive the closest attention of the medical expert.

The symptoms of secondary myelitis and sclerosis, following injuries obscure in themselves, are by no means so undetermined and vague as the too commonly accepted symptomatology of "concussion of the spine" would lead one to suppose. The characteristic signs have been carefully and minutely studied, recorded, and set forth by various authorities, among whom may be mentioned Charcot, Vulpian, and Leyden. Treatises based, like Erichsen's work, upon the evidence of railway cases are certainly the last sources of information from which one may learn to make a correct diagnosis and prognosis, and to escape being deceived by the voluntary or involuntary exaggeration and simulation so commonly observed in plaintiffs seeking damages.

Even in genuine cases, where unequivocal signs of secondary disease of the cord follow the infliction of violence, the prognosis drawn by medical experts is often needlessly severe. Recoveries from myelitis, meningitis, and sclerosis, with long-standing paraplegia, followed by spasmodic retraction of the legs, are by no means rare, as has been shown to be the case in Pott's disease by Leudet, Bouvier, Charcot, and Michaud. The cases cited by Dr. Hodges show that in some of the worst cases of so-called "concussion" a speedy recovery may take place.

In conclusion Dr. Curtis would propose the following definition of spinal concussion: The term denotes a condition resulting from external violence in which the patient is liable to be affected with certain definite and recognizable secondary diseases of the spinal cord, namely, myelitis, meningitis, and sclerosis.

DR. BIGELOW remarked that it would not be doubted that damages awarded for injuries are sometimes excessive. This is no new fact, and will be true so long as the nature and prognosis of injuries are uncertain, or the amount of their equivalent in money is determined by a jury.

The question that immediately interests us is a scientific one. Dr. Ellis objects to the term concussion of the spine. The objection is shared by surgical writers. So long ago as Holmes's Surgery, the article upon concussion of the spine was a remonstrance against the existing use of this term, and an enumeration of a variety of different symptoms and also of different lesions erroneously grouped under it. The paper read to-night is especially valuable in calling attention to the fact that the term concussion of the spine should not be used unadvisedly, to alarm juries and pervert justice. But it should not be forgotten that an injury, by whatever name we call it, may be a severe one; whether a real concussion of the spinal marrow, like that of the brain, or some other disabling lesion, obscure in character, and uncertain as to its sequences and results. The question with the surgeon is, of course, How much is the patient hurt? rather than, What is the name of the injury? and until injuries of the class we are considering can be better defined and measured than now, justice will occasionally suffer from the uncertainty and imperfection of medical knowledge.

Another consideration is connected with the patient. It is important that no injustice should be done him. It would hardly be argued in court, that because patients are sometimes impostors, therefore an injured man should be inadequately compensated. Again, when a plaintiff goes into court for damages, whether with intent to deceive or as the honest bread-winner of a family, he is encountered by the defendant with every stratagem of law and evidence. In fact, the usual practice of corporations is to try at once to settle with the less astute among the injured for a trivial sum. It is perfectly legal that they should do so. And it is also legal that the more astute among plaintiffs should try to secure large damages. And it should be remembered that in many of the relations of life men sometimes feel honestly better or worse according to the attitude they for the time occupy to a large sum of money.

It is a question whether railroads should not be occasionally reminded, in a practical way, of the necessity of care, especially in a country where government exercises so little control as here in their management. If damages were notoriously and habitually excessive, a remedy would doubtless be found in a restriction of their amount by legislation, in behalf of railroads, as has, I believe, been already done in the case of towns. The discussion this evening relates to a surgical term that has been recognized as an inaccurate one. If we abandon it, we must find, to supply its place, others that will designate more exactly the injuries hitherto somewhat loosely grouped under this one.

PAROTITIS IN FEVERS.

DR. LYMAN spoke of the case of an old lady with pneumonia, who had great enlargement of the parotid glands, which interfered with swallowing, and finally caused her death. Niemeyer refers to similar cases. Dr. Lyman had observed it occasionally in typhoid fever.

DR. C. D. HOMANS said that there were quite a number of soldiers with fever in the army who were affected with enlarged parotid as a complication, and that all these cases were fatal.

DR. HODGES remarked that the enlarged parotid presented itself occasionally at the end of an exhausting disease; he had seen it several times, and it had always been fatal.

DR. CHEEVER had seen it after an operation for ovariotomy, the patient dying on the fifth day; he had also seen it in one surgical case, where the death, however, was not so speedy.

DR. ABBOTT had observed this as a fatal complication in a girl eighteen years of age suffering from cancer of the stomach.

MONSTROSITY.

DR. FITZ showed a monstrosity which had been sent him by Dr. I. F. Galloupe, of Lynn. It presented a combination of cyclopia and anterior hydronephaloecele. The fetus corresponded in size with one of about seven months, and with the exception of the head and face was well formed. From the anterior portion of the cranium there projected a rounded, fluctuating tumor nearly two thirds the volume of the head of the fetus. Pressure upon the tumor caused a bulging of the anterior fontanelle, and a wave of fluctuation was transmitted to the same point. On the lower surface of the tumor at its junction with the head was a slightly depressed, smooth, glistening, and injected surface, at one portion of which was an opaque fibrous plate. The depressed surface was bounded by an elevated margin of an oval outline, in which were vertical yellow lines representing the meibomian follicles, and projecting from which were occasional delicate hairs, representing eye-lashes. A subsequent dissection of the sack, made by Dr. Whitney, showed that the fibrous plate above mentioned was a flattened, hollow sack with pigmented contents. Where the interior of the large cyst communicated with the interior of the cranium, the bones of the latter were somewhat everted. The face of the fetus was flattened and smooth from the attachment of the tumor down to the mouth. The lower part of the face was normally formed. There was no appendage present corresponding with the proboscis so frequently attached to cyclopians monsters.

Casts and crania from the museum of the Harvard Medical School were also shown for the purpose of illustrating the absence of the proboscis in the cyclopians fetus, and the variations in the seat and shape of the orbital cavity, with the corresponding changes in the nasal cavity which might occur in anterior hydronephaloecele.

In a letter written by Dr. Galloupe, it was stated that the mother considered herself to have been pregnant about seven and one half months. She was thirty years old, and had been delivered of a well-formed child at full term, and had also been delivered at seven months of well-formed twins. The delivery of the monstrosity was accomplished without difficulty, and an unusually large quantity of liquor amnii was present.

EXTROPHY OF THE BLADDER.

DR. C. B. PORTER exhibited a patient operated on by him for extrophy of the bladder. His remarks on the case are reserved for publication.

DR. BIGELOW said that the result in this case was remarkably good. He would, however, add that his own object in obliterating the cavity beneath the protecting flaps by dissecting off all the mucous membrane had been to prevent the accumulation of phosphatic deposit, such as he had observed when he had left a cavity. He thought that perhaps in this case the cavity might be still further obliterated, so as to bring the ureters directly opposite the orifice.

FIBROID PHTHISIS.

DR. F. C. SHATTUCK made some remarks on a case of fibroid phthisis, and showed the patient.

FRACTURED CALCANEUM.

DR. B. CUSHING reported a case of fractured calcaneum in a woman fifty-seven years of age, which he treated by extension for four weeks, with almost complete recovery. He also exhibited a cast which he had taken of the foot.

BOSTON MEDICO-PSYCHOLOGICAL SOCIETY.

WALTER CHANNING, M. D., SECRETARY.

PURSUANT to a call, Drs. J. B. Ayer, Cowles, Channing, Denny, Fisher, C. S. Folsom, N. Folsom, Jelly, and Whittemore met on the evening of January 6th to consider plans for the formation of a society to take psychological journals, and hold meetings to read and discuss papers on psychological subjects and to report cases.

After prolonged discussion, these plans were substantially agreed upon, and the society was organized with the above name. By-laws were submitted and adopted, which state that "the officers shall be a permanent secretary and treasurer, to be elected annually, and a president, to be chosen at each meeting. The meetings shall be held on the evenings of the first Thursday in each month, from October to June inclusive. There shall be a permanent committee on journals."

After the transaction of other business the society adjourned.

Recent Literature.

Lectures on Diseases of the Nervous System. By J. M. CHARCOT. Translated from the Second Edition by GEORGE SIGERSON, M. D., M. Ch., etc., of Dublin. Philadelphia: H. C. Lea. 1879. Pp. 263.

The writings of Professor Charcot, and perhaps this work even more than the rest, are too well known to the medical public to require any extended notice at this time. The lectures which make up this volume have been delivered at different times within the past few years at the great infirmary "La Salpêtrière," which owes its transformation from an obscure though immense poor-house into a great field for clinical research to Charcot's energy and intelligence. Though not all his brilliant pathological generalizations have passed unscathed through the mill of German criticism, yet it may be said with truth that he has written nothing which has not received respectful attention.

It is refreshing to be able to add that the translation is very creditably, even attractively, done, in spite of occasional Gallicisms, and as the book is cheaply published we hope that it will find a large circle of readers. Motives of economy undoubtedly prevented the reproduction of some of the excellent plates which accompany the original volumes. J. J. P.

Primer of the Clinical Microscope. By EPHRAIM CUTLER, M. D. Boston. 1879.

The compound microscope began its development in the shape of a simple tube about two hundred years ago; each deficiency was remedied as practical use

demonstrated the need; thus a stage, a mirror, mechanisms for coarse and fine adjustment, were added to the simple tube of Tortona, which was used as the so-called clinical microscope of to-day is.

This injudicious return to an old model is illustrated by a primer that combines ten pages of the simplest platitudes concerning the structure and use of the microscope with fourteen pages mostly occupied with accounts of work, so profound that no reliable observer has as yet been able to confirm it. When we add that no small number of inaccuracies are mixed up with the incompatibles mentioned, it will be seen that the *Primer of the Clinical Microscope* is a book which the beginner should shun.

A Treatise on the Theory and Practice of Medicine. By JOHN SYER BRISTOWE, M. D. Lond., Fellow and formerly Censor of the Royal College of Physicians, Senior Physician to and joint Lecturer on Medicine at St. Thomas's Hospital, etc., etc. Second American Edition, revised by the author, with notes and additions by JAMES H. HUTCHINSON, M. D., one of the Attending Physicians to the Pennsylvania Hospital, etc. Philadelphia: Henry C. Lea. 1879.

The second edition of this excellent work, like the first, has received the benefit of Dr. Hutchinson's annotations, by which the phases of disease which are peculiar to this country are indicated, and thus a treatise which was intended for British practitioners and students is made more practically useful on this side of the water. The early appearance of a second edition bears witness to the favorable reception given to the first, and we see no reason to modify the high opinion previously expressed with regard to Dr. Bristowe's work,¹ except by adding our appreciation of the careful labors of the author in following the latest growth of medical science. The chapters on Diseases of the Skin and of the Nervous System, with a new one on Insanity compiled from the best sources outside of the author's own long experience, and the valuable portion relating to General Pathology, aid greatly in completing an exceptionally good book for purposes of reference and instruction.

— Dr. Brigidì, in *La France médicale*, has noticed the following pathological changes in fatal cases of hydrophobia: Great hyperæmia of brain and spinal cord, as well as membranes, and in one case serous effusion in the subarachnoid spaces; enlargement of the cerebral and medullary cells, which were found to be full of vibrios. Similar appearances were found in the blood, mixed with bacteria, and extensively marked in the circumference of the vessels. The central medullary canal was distended, and full of the same granular substance. Dr. Brigidì does not pronounce on the question as to whether the development of the vibrios has been a cause or an effect. He believes that the morbid process observed in the nervous centres is of an irritative and degenerative nature, and that under the influence of the vibrios it may spread with extreme rapidity.

— According to the *Union médicale*, 97,790 deaths occur daily. By way of compensation the number of births is computed at 104,800 *per diem*.

Medical and Surgical Journal.

THURSDAY, FEBRUARY 5, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Osgood and Company, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, OSGOOD AND COMPANY, Boston, Mass.

DR. BOWDITCH'S RETIREMENT FROM THE MASSACHUSETTS BOARD OF HEALTH.

OUR readers will find in our present issue the text of Dr. Bowditch's letter to the governor of the State, resigning his position as a member of the present hybrid and polysyllabic Board of Health. This letter has not hitherto been published, but it is very proper that it should see the light. Dr. Bowditch's reasons for resigning are two in number, though practically one in reality. He has, as is well known, been opposed from the first to the reorganization and amalgamation of the board with other boards in its present form, and a six months' trial has but served to strengthen his convictions. The duties of the office have been trebled under the present *régime*; they are performed gratuitously, and, the pursuit of his private professional practice being still a necessity, he finds it quite out of his power to devote to them the time requisite for their conscientious performance. In general he feels strongly that the education of the people in sanitary matters will not be as efficiently accomplished by the present organization. His views will be found more fully expressed in a paper in a late number of the JOURNAL. We suspect time will show that there is much of truth in them, and that either the proper work of the Board of Health will be slighted, or it will be relegated to one or two individuals.

However this may be, we very heartily regret any causes which deprive the State of so faithful and active an officer, and "state medicine" of so able, so far-seeing, so earnest, and withal so temperate an official advocate as Dr. Bowditch. For the past twenty years he has been in the front and thick of the fight with "the pestilence that walketh in darkness, and the destruction that wasteth at noonday;" doing much himself, and ever striving himself and encouraging others to do still more, for "the improvement in human health, and for the lengthening out of human life of each individual man or woman." In his own words, we may remind our readers that "no object can be nobler, none more deserving the attention of learned men, or of philanthropists or statesmen."

The first meeting of the Massachusetts Board of Health was held a little more than ten years ago, September 15, 1869, and the board organized itself, with Dr. Bowditch as chairman and the lamented Dr. George Derby as secretary. In view of what has since been accomplished, we wish we had room for the whole of the short address of the chairman to his colleagues on that occasion; it is a pledge of the work which has

since been done, and is the utterance of "an understanding mind, a buoyant and willing heart."

Preventive medicine, the Brighton abattoir, the abolition of nuisances, the purification of sources of water supply, the war waged against the pollution of streams, the establishment of local boards in the various cities of the commonwealth, and finally the annual reports of the State Board are but a few of the many mile-stones marking the toilsome track of this sanitary pilgrimage of the last ten years, and are at the same time so many accumulated responses to the hope of the chairman expressed at that first meeting, without misgiving, "that this board will faithfully and in an able manner perform its duties, and that thus it will become a real blessing to our State, not only at the present time, but long after every member of it has died. It will assuredly be such if we, the necessary originators of its various details, only look at our duties in the light of the broadest philanthropy and, as far as in us lies, the wisest statesmanship, and finally with all the knowledge that modern science can at present give us."

Dr. Bowditch's contributions to the literature of hygiene have been numerous, when we remember that he has been constantly engaged in the labors of a large and very responsible practice, and some of them have been of the very first value. His name will be always associated with the topographical distribution of consumption exhibited by soil moisture as one of its causes, a theory so ably presented in his address before the Massachusetts Medical Society at its annual meeting in 1862, and subsequently independently verified by investigations under government authority in England in 1865-66.

This subject he presented in a popular form in some short articles in the *Atlantic Monthly* for January, February, and March, 1869, entitled Consumption in America. He contributed a report on climatology and epidemics in Massachusetts, 1868-69, to the Transactions of the American Medical Association, and an article on Hippophagy to the *New York Medical Journal* for August, 1878.

Had he written nothing else we should still wish to render him our tribute for his contribution to the Report of the Board of Health for 1872 on Intemperance as governed by Cosmic and Social Law, an Analysis of the Correspondence on the Use and Abuse of Intoxicating Drinks throughout the Globe, which was presented to the legislature in 1871. His subsequent treatment by those fanatics from whose views he differed gave added force to his common-sense position that intemperance does not consist in the abuse of alcohol alone. Another article on this subject, called Intemperance in New England: How shall we Treat it? was published in this journal in 1872.

He contributed to the Board of Health Report for 1874, Preventive Medicine, or the Physician of the Future; to the Report for 1875 a paper on Inebriate Asylums or Hospitals; and he also delivered an address at the annual meeting of the American Medical Association in 1876, on State Medicine and Public Hygiene.

Dr. Bowditch has well earned the right to retire from public office, and to withdraw from the State his valuable services, but he leaves to his late colleagues the difficult task of making good his loss, and to the commonwealth an organization so firmly established, we may be allowed to hope, in its own usefulness and in the confidence of the people, that it will long survive any individual member. Neither chance nor change can rob the community of the sterling value of a good example of enthusiasm, devotion, and sagacity.

THE CHILDREN'S HOSPITAL IN BOSTON.

WE are glad to learn that an effort has been made to raise money to enlarge the Children's Hospital in this city, and that the appeal so far has met with an unusually generous response.

This charity was started ten years ago, beginning in quite a small way. The foundation for a well-organized institution was laid in the selection of an influential board of managers, an efficient medical staff, and excellent management under the direction of one of the ladies of the Sisterhood of St. Margaret. A sufficient amount of money was contributed for the running expenses of the hospital, and excellent work has already been done there.

A certain amount of opposition was encountered at first from those who felt that such a charity was not needed in a city with two large and well-appointed general hospitals.

Although the treatment of the diseases of children is in no sense a pure specialty, the nursing needed, the diet, the hours for sleep and meals, and the management of convalescents make it convenient that as patients, children be classed separately from adults.

In Paris, where specialism has never met with much favor, the Hospital for Sick Children is a large and important institution. In Vienna, where special hospitals do not flourish as a rule, although it is the home of the specialist, the Children's Hospital is one of the prominent medical attractions.

The great Ormond Street Hospital in London is too well known to need a mention. It has given us Dr. West's excellent book on the Diseases of Infancy and Childhood. The result of this separate accommodation for this class of patients is that the diseases peculiar to children are probably more thoroughly studied and better taught in Paris and Vienna than anywhere else. Those of us who have profited by the clinics in these hospitals certainly appreciate what an advantage to the medical community such an institution here would be.

Boston is of course not to be compared with Vienna, Paris, or London; but if a large and well-appointed children's hospital has proved to be a need in Washington, it would certainly seem to be wanted in our city, — a city with a relatively large pauper class, and a city which is the medical centre of quite a large and populous area.

The first decade of the existence of the Children's Hospital here seems to have thoroughly demonstrated its *raison d'être*. Some fifteen hundred patients have

been treated, and the number has been limited by a lack of accommodation rather than by a want of applicants; many patients have been referred to the hospital from the general hospitals and from other institutions. A convalescent home started by a number of ladies interested in the hospital has been connected with it for the past few years, and is open in the summer to convalescents from the hospital and to those patients who need fresh air and good nursing more than clinical treatment.

Any one who has had any acquaintance with the working of the hospital will testify to the unusual excellence of the nursing, which in every way is a model for similar institutions.

Altogether the "plant" of the charity is a remarkably good one. The present building, however, is entirely unsuited for a hospital, being a private house without proper means of ventilation or arrangements for isolating patients.

The plan of the managers is, we believe, to put up at some suitable spot a cheap building, large enough to accommodate more patients than can be treated in the house now used.

The managers of the hospital will certainly have the hearty good-will of the profession in their undertaking.

MEDICAL NOTES.

— Paul F. Mundé, M. D., of New York, has been elected lecturer on gynaecology in the Dartmouth Medical College.

— David L. Webster, Esq., of Boston, a very valuable member of the old Board of Health of Massachusetts since 1874, has been appointed to the vacancy in the present board caused by the resignation of Dr. Bowditch.

— Richard Frothingham, Esq., a member of the old board since its organization, died a few days since.

— Dr. Edward F. Hodges has lately gone from Boston to Indianapolis to continue the practice of his profession in a position of responsibility, for which his high personal character and his professional attainments eminently qualify him.

— It is reported from Memphis that all the recommendations of the committee appointed by the National Board of Health are being carried out.

— The recent visit to Boston of Dr. J. Marion Sims was made the occasion for a reception in his honor by Mrs. Clement, whose contributions to art literature are so highly valued, and who dedicated her work on Painters, Sculptors, Architects, and Engravers to the great gynaecologist, as a token of "respect, gratitude, and affection." Mrs. Clement's reception was a graceful compliment to her guest, and a large number of physicians gladly availed themselves of her hospitality, among them Drs. Holmes, Bowditch, Williams, Reynolds, Cabot, Thorndike, and about seventy others. Dr. Sims, during his short stay in Boston, was the recipient of marked attention. He visited the Massachusetts and City Hospitals, was present at Dr. Holmes's lecture to his class at the Harvard Medical School, and subsequently addressed

the class himself. He also held a number of consultations in Boston and the vicinity.

— From the London *Lancet's* review of the year 1879 we take the following: Another great subject that has excited attention during the year is Professor Bigelow's operation of litholapaxy, — that is, crushing a vesical calculus by the lithotrite, and removing the fragments by suction at one sitting. This is a new departure in lithotripsy, and has already made much headway.

— Dr. C. D. Phillips, of London, has recovered from the London and Southwestern Railway, for damages resulting from an accident on their road, the satisfactory sum of \$80,000.

WASHINGTON.

— The profession of the District is watching with great interest the progress of a proposed bill for taxation, in which the medical practitioner is to be taxed fifty dollars per annum for his license or privilege. There seems to be a determination on the part of merchants and others who are to be heavily taxed for the carrying on of their business that physicians shall feel the burden of a similar weight, but it is hoped that a better understanding of the subject will prevail, and the imposition not be enforced. If it is it will drive some worthy men, out of the profession, and enable others, by ways that are dark, to evade the law without injuring themselves, and seriously affect the practice of their colleagues; there are many men holding office as clerks who can afford, by receiving the means of a livelihood from the government, to remove all vestiges of business from their professional advice, and rely upon the gratitude of their friends and patients to supply them with gratuitous *douceurs* which will fairly set off the asked-for fee.

LONDON.

— Dr. J. Milner Fothergill, who has incurred the displeasure of the *British Medical Journal* on account of his incautious comments upon the status of the medical profession in Great Britain, says in a letter to the *Philadelphia Medical Times*, "I know nothing of club-life, but since the notices of my letters have appeared in the *British Medical Journal* I have had a good deal of information afforded to me about the social position of the profession; and it appears that at the very select clubs doctors are not eligible for election, and that comparatively very few are to be found in the literary Athenæum Club, — the home of literature. If the profession are really satisfied with their social position, then, surely, a great deal that I have read in the medical journals for the last twenty years was unnecessary and unjust. I believe that up to the time of the Crimean War an assistant surgeon in the navy could be flogged; and it has only been from its necessities, and not from its voluntary action, that the war office has given anything to the profession."

With regard to specialist consultants in London, Dr. Fothergill continues as follows: "Indeed, it is now almost essential to success that a man who de-

cides to become a consultant shall devote himself specially to one subject, write articles on it, write a book on it, and have his name known in connection with that subject, so that the general practitioner shall know of him as a specialist in that department, and consult him accordingly. It is the quickest way to become known, and brings in patients without much delay. Then, of course, the growth of special hospitals has largely fostered this attention to special departments; the specialist heads for the special hospital, which welcomes him, and is glad to have him as an addition to its staff, while an appointment to a special hospital expedites the specialist's progress towards practice. By such means a number of men readily succeed in the world who in by-past days would have a long, hard struggle, unless they had the good luck to become attached to a general hospital. The staffs of general hospitals hunt in packs; the surgeon calls in his physician colleague, and he again, if required, his obstetric colleagues. Of course this is done, more or less, all the world over. Specialists, in order to attempt the same thing, are largely arranged in groups, and send patients back and forwards, and so are of mutual advantage to each other. There are men who will poach, but I very much doubt if that pays in the long run. Then, of course, each specialist cultivates the general practitioners who consult him or call him in, — invites them to dinner, and presents them copies of his books.

"When the general practitioner wants a consultation he pitches upon some one known to him, or on some one whose name is associated with the disease under which the patient is suffering. In many cases the choice is determined by the patient, who prefers the man with the better known name. Then the patient comes up to town, or the consultant is called down, as the case may be. At other times the patient goes to London to see a certain authority without the cognizance of his ordinary medical attendant, and then trouble is looming. The consultant takes a different view of the case, or sees it in a later phase, and uses different language about it from that used by the ordinary medical attendant, and then there is discord. Duplicity is innate in some persons, while others, again, delight in making mischief. So the consultant has often some difficulty in finding out the patient's ordinary doctor and communicating with him, so as to prevent any unpleasantness. Then some doctors are more 'touchy' than others, and readily take offense, so that it is a delicate matter to interfere with their patients when they turn up in one's consulting-room. And then I fear — but now I know the editor of the *British Medical Journal* has his watchful eye upon me — there are men to be found who are so attractive that they soon convert the patient who comes to them for a casual consultation into a regular patient, and the patient's general attendant sees him or her no more. Of course much of this is due to the inclinations of the patients; but in some cases there must be something in the ways of the consultants, or otherwise some men are much maligned. Often the consultant is placed in a very delicate position by want of

frankness in a patient. Some men think they have a vested interest in the patient who once consults them, and are sore if the patient sees any other professional man with or without their cognizance. . . . The specialist is paving the way for specially educated consultants. The old plan was largely to commence in more or less general practice, devoting attention, perhaps, to some subject more than others, and then in time, as skill increased and brought with it repute, the experienced individual was called in to give counsel in the practices of other men. But now a man prefers to select some particular department, and sedulously cultivates himself in that direction: goes abroad to see the practice of celebrities in that branch; learns all he can; reads all the books on the subject, writes articles on it, or reads papers at societies, or joins in discussions on the papers read by others; translates a foreign work on the subject, or perhaps ventures to write one himself. By so doing he certainly does acquire a very great deal of knowledge on the subject, and if he is a man of sound good sense, and keeps himself well up with medicine generally and his own subject particularly, then he is a very useful member of society. This last class of men is decidedly on the increase at the present time, and the line of demarkation betwixt the general practitioner and the specialist consultant is becoming more defined every year."

Miscellany.

ANTISEPTIC SURGERY.¹

LECTURE BY PROFESSOR LISTER.

THE second case brought before his audience was that of a woman from whose back Lister had removed a recurrent fibroid tumor twelve days previously. The tumor originated fifteen years before, had been removed, and had returned several times at intervals of three or four years. When Lister removed it its mass was large and was firmly adherent to the spinous processes of four of the dorsal vertebrae, which processes Lister cut away almost in their entire length, as well as a considerable mass of spinal muscles in their vicinity, leaving a large hollow in the middle of the back. In order to close in this deficiency he performed a plastic operation, making use of lead buttons with an original modification. For details of this portion of the operation, interesting as they are, we must refer our readers to the *Lancet* of December 20th, which gives the lecture in full. The sutures were of thick silver wire with intermediate stitches here and there of carbolized silk or purified horsehair. Intervals were left for rubber drainage tubes. Relaxation of the skin was provided for by arranging the bandage which confined the gauze dressing in a figure-of-eight fashion about the shoulders, thus keeping them drawn backward. Through "a rare reactionary hæmorrhage," the patient that afternoon lost a good deal of blood, became restless, and tossing about tore out several of the stitches, thus producing a gap at the base of the flap, about two inches in diameter, and exposing the cavity of the hollow wound. Lister directed especial

attention to these appearances at this stage of the case. Holding his hand over the portion of dressing corresponding to this wound while bandages were being cut and the edges of the dressing raised, he removed it only when the spray had gotten fairly under the dressing and had reached the region of the wound. Then exposing the latter he said, "We used to say before the introduction of antiseptic treatment that if a wound did not unite by first intention suppuration was established in about four days in the adult in cool weather, and in about three days in a child in warm weather. Here, twelve days have elapsed since the operation. Union by first intention was impossible throughout a large extent of this wound. Yet observe, we have no suppuration. I wish some of our friends who doubt the good effects of the antiseptic treatment could see a fact of this kind. Twelve days with a great hollow wound like this, with an opening leading freely into it and the tissues exposed, yet not one drop of pus! As in the case of empyema, I again venture to affirm that the merely serous discharge upon this dressing could not have occurred without antiseptic treatment of some kind; not necessarily the kind we use, but something effectually answering the purpose of keeping putrefaction out. That the dressing here employed has been thus effectual allow me to give you evidence. That dressing has been on the patient two days; you see the oiled-silk 'protective' perfectly free from the dark discoloration which it would acquire within such a period if putrefaction occurred, and you can ascertain for yourselves that it has no odor of putrefaction. The dressing, then, has been truly antiseptic. Observe now the entire absence of inflammation about this wound. It has been so from the first. The day after the operation we saw that the upper part of this flap for about two inches in breadth presented a livid discoloration, and looked as if it were about to lose its vitality. I remarked that it did not follow that there would be any death of tissue, although I believe any practical surgeon who had seen the case then would have said that under ordinary treatment there must have been an extensive slough. I did not at all despair of this part, to a large extent at least, recovering itself, because, even supposing any portion of tissue has lost its vitality through defective circulation, and suppose that piece of tissue so dead does not putrefy, it does no harm to its neighbors from the mere fact of its being dead, any more than the dead intestinal tissue of the catgut with which we tie our arteries. Catgut is absorbed by the living tissues round about, and so may other dead tissues be absorbed and not in the least offend their living neighbors; whereas, on the other hand, if it does putrefy, the dead piece, being putrescent, becomes a source not only of irritation, but of caustic action, to the parts immediately adjacent. For if one portion of tissue has lost its vitality through interference with the circulation, you may be quite sure in the immediate vicinity other parts will be weakened in their vital power from the same cause, just as in the case of senile gangrene, where we know the liability of gangrenous inflammation to spread. But here you see that the once livid patch has to a large extent recovered itself. It remained discolored for several days, but we found on firm pressure with the tip of the finger that the color could be dispelled, and it slowly reappeared when the pressure was removed,

¹ Concluded from page 116.

showing that the blood was still fluid in the vessels; whereas, if the tissues had been dead, the blood would have been coagulated. There now remains only a little piece of the extreme margin of the flap, an inch and a half long, and about half an inch broad, which is not obviously alive. This little bit has actually lost its vitality, but here it remains after these twelve days still firmly attached to neighboring parts, the stitches which connect it with the living skin still holding. It has neither induced suppuration, nor excited the faintest inflammatory blush in the surrounding skin. There is not even an absolutely defined line of demarcation. That, again, would have been an impossibility without effective antiseptic treatment. But with such treatment it is a possibility, for I have seen in larger sloughs than this that this piece of dead tissue may be absorbed and never separate at all.

"One other point about this wound is worthy of attention. This window, leading into the cavity, was at one time considerably bigger than it is now. It became incrustated at its borders by exuding liquor sanguinis, which, coagulating, formed a solid ring within it, and this exudation of liquor sanguinis has gone on, producing a broader and broader ring. The parts first formed, remaining free from putrefaction, have undergone organization, including vascularization, and the newly-formed vessels have continued to pour out plasma. And now, if we turn up the superficial layer of the coagulum at its outer margin, we see disclosed a ring of cicatrix. That is to say, the organization of the ring of coagulum has assumed the character of epidermic formation in the vicinity of the preëxisting epidermis of the cutaneous margin. And this process of cicatrization has been going on without the production of any pus, and even without the formation of any true granulations. I never happened to see anything exactly corresponding before. But this is, doubtless, simply because I never before had the opportunity of studying a window like this in a piece of skin stretched over a cavity. For we have here only a peculiar instance of what we are familiar with under antiseptic treatment, the organization of blood-clot and cicatrization proceeding under the superficial layer of the coagulum without the occurrence of suppuration or true granulation. It is by virtue of the same process of progressive exudation and organization of plasma that the cavity of the wound is being constantly reduced. We see, on looking through the window, that the floor of the cavity is not so far below it as it was; the hollow is becoming constantly shallower. Now, all this presents what must seem to those who have not witnessed it a marvelous and incredible contrast with the old mode of healing by granulation and suppuration, which must infallibly have occurred without antiseptic treatment.

"I now reapply the dressing. The protective, dipped in the one-to-forty watery solution to destroy the septic property of any dust adhering to it, is applied over the healing wound. Immediately over this is placed a piece of the carbolic gauze, dipped also in the lotion, to insure that it is actively antiseptic when applied, for the dry gauze cannot be trusted in this respect, and over this the regular gauze dressing of ample dimensions. Remember the immense importance of having the protective overlapped well on all sides by the gauze. The protective, having nothing antiseptic in its composition, must be overlapped just as if it were itself a wound.

"The attainment of the results which you have seen in this case depends not only on the efficacy of the antiseptic measures used, but also upon the use of an efficient protective, as we term it; that is to say, a layer of material employed to protect the healing part from the irritation of the antiseptic itself. And with reference to this point I may mention that we have now a considerably better protective than we had some time ago. It still consists essentially of oiled silk, varnished on both sides with copal varnish. The copal varnish is the principal and most important agent in this protective for keeping the carbolic acid out; it is much less permeable to carbolic acid than oiled silk is, although oiled silk itself is much less permeable to acid than gutta-percha or caoutchouc. Some persons object to this protective as being too thick and substantial. They little know what a mistake they thus make. When at the temperature of the body it becomes soft and pliable. Without an effectual protective we should not have had the results evident in this case. A carbolic-acid dressing acting directly on the tissues of the exposed wound would have caused granulation and suppuration, 'antiseptic suppuration,' caused by irritation. If the gauze dressing had been applied directly to that piece of dead tissue it would have impregnated it with the pungent acid, would have stimulated it and its living neighbors, and urged them to granulation and suppuration, and we should have had a piece of dead tissue already separated by suppuration.

"Again, if we had not used a pretty efficient protective, we should not have seen the blood-clot organized and cicatrizing without suppuration at the edge of the window in the skin. We should have seen it with a granulating and suppurating margin. I am induced to speak on this point because I believe the protective is often as yet imperfectly understood. A very eminent surgeon was round my wards some months ago, and he told me he had never seen the organizing blood-clot. I took him to two cases in which it was occurring. He was a man of scientific precision, and at once said, 'These cases are enough for me; I know from this time that an exposed blood-clot may become organized.' How was it he had never seen it, having practiced antiseptic treatment with great efficiency for years? The truth was, as he told me, he had not thought the carbolic acid particularly irritating, and he had never used any protective at all, and therefore had never seen an organizing blood-clot.

"I had sent to me some time ago by a very distinguished Russian surgeon this beautiful-looking article, this transparent film, which he told me he now always used in preference to our protective,—a most lovely thing, certainly, enough to charm us to use it by its mere beauty. But I found it would not stand the test which will enable you always to ascertain the quality of a protective. I took a piece of it, and put upon the middle of it a little bit of lint soaked with one-to-twenty carbolic-acid lotion, and left it a while; in the course of about half an hour, on applying the tip of my tongue to the other side, I perceived the pungent sensation caused by carbolic acid, showing that it had already gone through it: whereas, with a piece of this properly made protective, treated in the same way, you would find, after the lapse of three or four hours, absolutely no trace of the acid. Therefore, although this so-called protective is very

pretty, it is scarcely a protective at all in the sense in which we use the term. It will keep the wound moist, and thus prevent the dressing from striking to it, but that is nearly all it will do.

"But worse remains to be told of this elegant article. The chemist who sent me the samples informed me that it contained thymol and salicylic acid in its composition; in other words, it was not only inefficient as a protective against the antiseptic, but it was actively antiseptic in its own substance. And he added it could be made up with carbolic acid, showing that he had no idea whatever of the object for which we use the protective. It has been said sometimes that our dressings irritate wounds. The wound you have just seen is an instance to the contrary. It is not irritated; it is healing kindly; and not only so, but it shows very much less marks of irritation than you could get with any ordinary treatment that has been devised. But if surgeons use the antiseptic agent, whatever it be, in such a way as to act directly on the tissues, they will necessarily have their wounds more or less irritated, according to the nature of the antiseptic they employ.

"But useful as a protective is in promoting the best kind of healing under an antiseptic dressing, it would be infinitely better to use no protective at all than to employ it amiss; for in proportion to the efficiency of the protective in excluding the irritation of the antiseptic is its power also to exclude its antiseptic virtue, and thus to conduct putrefaction inward to the wound, unless it be overlapped well on every side by the really antiseptic element of the dressing."

This case resulted as favorably as Lister had prognosticated. When the lecture was published the slough had already become partially absorbed without suppuration. The stitches which attached the flap at the site of the slough still retained their hold, and the border of the mass of dead tissue thus kept in contact with living skin had undergone a process of organization, that is to say, of substitution of living tissue elements for the dead which they had absorbed, exactly similar to that which had occurred at the border of the window in the skin. "And thus, without the slightest trace of suppuration, and without the occurrence of granulation, a cicatrix about one sixth of an inch in breadth had come to occupy the place of the upper border of the slough."

An editorial in the number of the *Lancet* which contains Lister's lecture says: "Whatever be the amount of accurate research required to prove or disprove Lister's germ theory, it is with the results of his practice that we are mainly concerned, and we doubt if figures will aid us much in reaching a conclusion on the subject. We believe that if Mr. Lister's system possesses the advantages claimed for it, it is merely a question of time as to when it will take its place as the established practice of surgeons, and this time will neither be hastened nor delayed by statistics such as those which have at present been presented to the profession. We admit without hesitation that the result of Mr. Savory's and of Mr. Bryant's hospital practice is most satisfactory, but we are equally sure that patients under certain very unfavorable hygienic conditions have been enormously benefited by the employment of the Listerian system of dressing. The testimony of British surgeons, not only in this country, but in India and other parts of the world, together with the evidence of practitioners

engaged in some of the Continental hospitals, is conclusive on this point; in fact, the Listerian system may be said to be the outcome of defective sanitation, for Mr. Lister evolved his principles and practice of surgery in the wards of the Glasgow Infirmary, at a time when the insalubrity of that institution was notorious.

"We have seen the failure of too many surgical modifications for the dressing of wounds to be disposed to take up any novel system of treatment without due consideration. This, however, was not by any means our only reason for withholding the expression of a favorable opinion of Listerism, for it has long been evident that this was not merely a matter of treating wounds, but that important principles were involved. If Listerism in the smallest degree guards our patients from any preventable dangers, after injuries or operations, duty clearly points out the road we should follow.

"After the most careful consideration of the subject, we believe Listerism has undoubtedly diminished the mortality and the danger to patients situated under unfavorable hygienic conditions after surgical operations; and holding this belief we may argue from the greater to the less, and assert our conviction that this same system is capable of preventing septo-pyæmia in patients under almost all circumstances. We hold, therefore, that Listerism is destined to be the surgery of the future; for, however difficult the details or length of time required to carry out these principles in individual cases, it must and will prevail, because it guards our patients from unquestionable dangers."

In a letter to the *British Medical Journal* Mr. Holmes says, "The sum of the whole matter is this: There is, I believe, a very large number of practical surgeons who, like myself, are thoroughly convinced of the value of drainage and antiseptic dressings, and who, like myself, are glad to confess their obligations to Mr. Lister's teaching, but who are not convinced by the evidence of the relative superiority of his own method of applying them, which he has produced up to the present time. Far, indeed, from being prejudiced against either the method or its author, we are warm friends of both, and only anxious to do the best we can for our patients. We believe the Listerian treatment rests upon and is inseparable from the germ theory. We see no proof of that theory in the reasoning heretofore adduced by Mr. Lister or Professor Tyndall. Nor do we see any proof of it in the novel phenomena on which Mr. Lister rested his chief argument at the late discussion, since, whatever reception we give to such facts, — if we allow them to be as absolutely unheard of as Mr. Lister claims, yet they are only previously unobserved phenomena in the healthy process of union, — they do not touch the question of the germ theory. Still less can we allow that a question so difficult and so purely physical can be settled by a bare enumeration of death-rates. But real statistics, showing the normal progress of cases treated by the Listerian, by the simpler antiseptic, by the open method with drainage, and on other plans, if they showed a specific difference in the cases treated by the first method, would be of great importance toward a settlement of the question. If it be too much to hope that the surgeons of King's College Hospital (Lister's hospital) will — as they certainly could — collect such data, may we not look for them from some other quarter?"

DR. H. I. BOWDITCH'S LETTER OF RESIGNATION FROM THE STATE BOARD OF HEALTH.

BOSTON, January 20, 1880.

HIS EXCELLENCY, JOHN D. LONG, GOVERNOR OF MASSACHUSETTS:—

SIR,—I wish respectfully to resign my office of member of the Massachusetts State Board of Health, Lunacy, and Charity. I do this with regret, but I feel compelled to do it for the following reasons:—

First. It is impossible for me to attend to the duties imposed upon me by the law establishing the board without neglecting my profession, upon which my family depends for its support. These duties have been more than trebled under the new *régime*, and I have been obliged to give up all thought of attending to the greater part of them. I have tried the experiment for six months, and I am unwilling, and it is not right towards the State for me, any longer to hold any office, the duties of which I am obliged thus systematically to ignore.

Second. I objected very strongly to the union of the board with any other. I knew that the proper education of our people in sanitary matters would require the full attention of all the seven members of the board. I felt persuaded that nothing but evil would happen to our board if it should have put upon it such

wide and multifarious duties as were performed by the Board of Charities, especially if, superadded to them, should be given the care of the lunatic hospitals and lunacy in Massachusetts. The experience of the past six months more than convinces me that I was right in making that protest. I believe if the present law remains upon the statute-book the public health will not be promoted as it would be were the board as untrammelled as it was up to July, 1879; and as I see no chance, at present, for any change in that law, I herewith resign my commission as an officer of the commonwealth. I remain, with sentiments of high respect,

H. I. BOWDITCH.

LETTER FROM DR. POLK.

MR. EDITOR,—I have just received a letter from Dr. C. G. Polk, of Philadelphia, in which, referring to my article published in the JOURNAL, January 15th, he says: "Of course you know that the statement that I was professor in the Eclectic College was an unmitigated falsehood, although my name did appear in the announcement."

Will you be so kind as to publish this denial as a matter of justice, and oblige,

Yours very truly,

R. T. EDES.

REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 24, 1880.

Cities.	Population estimated for July, 1879.	Reported Deaths in each.	Deaths under Five Years.	Percentage of total Deaths from				
				The Principal "Zymotic" Diseases.	Lung Diseases.	Diphtheria and Croup.	Scarlet Fever.	Typhoid Fever.

Two thousand three hundred and twenty-two deaths were reported; 914 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 511, consumption 378, lung diseases 295, diphtheria and croup 211, scarlet fever 89, measles 45, typhoid fever 33, diarrhoeal diseases 40, whooping-cough 31, malarial fevers 20, erysipelas 18, cerebro-spinal meningitis 11, small-pox 11.

From *measles*, New York 33, Brooklyn three, St. Louis two, Philadelphia, Chicago, Pittsburg, Lowell, Lynn, Holyoke, and Northampton one. From *whooping-cough*, New York and Boston six, Philadelphia, Brooklyn, and New Orleans four, Pittsburgh two, Chicago, St. Louis, Cleveland, Gloucester, and Brockton one. From *malarial fevers*, New York 10, Brooklyn and St. Louis three, District of Columbia two, Milwaukee and Charleston one. From *erysipelas*, New York six, Cleveland four, Philadelphia two, Brooklyn, Baltimore, New Orleans, District of Columbia, Milwaukee, and Providence one. From *cerebro-spinal meningitis*, New York, Chicago, and Cincinnati two, Philadelphia, Milwaukee,averhill, Fitchburg, and Quincy one. From *small-pox*, Worcester five, Philadelphia four, District of Columbia two. From *typhus fever*, Philadelphia and Chicago one. One death from typhus fever was reported in Philadelphia and in Chicago; one death from hydrophobia and one from tetanus were reported in New Orleans; scarlet fever was more prevalent and malignant in Cleveland, less so in Providence. Small-pox is reported as apparently "stamped out" in Baltimore. Influenza has become very prevalent in Wakefield, Mass. The death-rate of colored persons in the District of Columbia was nearly double that of whites.

The total number of deaths, and especially the deaths under five, show a considerable increase over the previous two weeks. There were fewer deaths from lung diseases, and many more from consumption. The mortality was increased from all the principal "zymotic" diseases except typhoid fever, which was without change; small-pox, measles, scarlet fever, and diphtheria were much more fatal. In 37 cities and towns of Massachusetts, with an estimated population of 1,018,610 (population of the State about 1,650,000), the death-rate was 20.58 against 20.89 and 20.65 of the previous two weeks, scarlet fever, whoop-

ing-cough, and diarrhoea having been more fatal, lung diseases less so.

For the week ending January 31, in 143 German cities and towns, with an estimated population of 7,523,410, the death-rate was 27.2 against 27.5 and 26.5 of the previous two weeks. Three thousand nine hundred and thirty-five deaths were reported; 1753 under five; pulmonary consumption 542; acute diseases of the respiratory organs 510, diphtheria and croup 174, scarlet fever 95, measles and *röteln* 63, whooping-cough 57, typhoid fever 56, puerperal fever 26, small-pox and typhus fever three. The death-rates ranged from 16.6 in Carlsruhe to 36.2 in Augsburg; Königsberg 30.2; Dantzig 24.3; Breslau 21.8; Munich 29.8; Nürnberg 29.3; Dresden 26.6; Berlin 26.0; Leipzig 26.1; Hamburg 29.3; Hanover 24.1; Bremen 23.5; Cologne 33.4; Frankfurt 27.7. For the same week, Vienna 33.0; Prague 36.7; Paris 33.4.

For the week ending January 10th, in the 20 English cities with an estimated population of 7,499,468, the death-rate was 24.0 against 29.1 and 27.4 of the previous two weeks. Three thousand four hundred and forty-four deaths were reported: acute diseases of the respiratory organs 455, whooping-cough 182, measles 131, scarlet fever 126, fever 44, diarrhoea 30, diphtheria 19, small-pox (London eight, Bristol one) nine, showing a striking diminution of deaths from lung diseases, an increase in measles and small-pox, and a decrease in diarrhoea and diphtheria, scarlet fever remaining about the same. The death-rates ranged from 15.8 in Oldham to 35.5 in Plymouth; London 25.0; Bristol 26.4; Birmingham 23.3; Leicester 17.7; Liverpool 20.7; Manchester 25.0; Leeds 19.8. In Edinburgh 22, Glasgow 23, Dublin (small-pox five deaths) 41. In the 20 chief towns of Switzerland, with an estimated population of 462,576, 240 deaths were reported and 233 births: acute diseases of the respiratory organs caused 33 deaths, pulmonary consumption 16, diarrhoea of children seven, diphtheria and croup seven, whooping-cough five, puerperal fever five, fever two, erysipelas, measles, small-pox one, scarlet fever none. The death-rate was 27.5 against 26.3 of the previous week; Geneva 24.3; Zürich 23.2; Basle 24.5; Berne 36.8; Lausanne 25.8; Vevey 11.3.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JANUARY 24, 1880, TO JANUARY 30, 1880.

HEGER, A., major and surgeon. So much of the order as directs him to proceed to San Antonio, Texas, on or before February 1, 1880, is amended to read on or before February 20, 1880. S. O. 19, A. G. O., January 26, 1880.

WHITE, C. B., major and surgeon. His leave of absence on surgeon's certificate of disability, granted him July 24, 1879, extended six months on surgeon's certificate of disability. S. O. 20, A. G. O., January 27, 1880.

TREMAISE, W. S., captain and assistant surgeon. His extension of leave of absence on surgeon's certificate of disability of November 11, 1879, further extended twelve months on account of sickness, with permission to go beyond sea. S. O. 18, A. G. O., January 24, 1880.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE WEEK ENDING JANUARY 31, 1880.

PASSED ASSISTANT SURGEON P. FITZSIMMONS from the Naval Hospital, Yokohama, Japan, and to return home and wait orders.

PASSED ASSISTANT SURGEON J. R. WAGGENER detached from the receiving ship at Boston, and ordered to the U. S. S. Vandalia.

ASSISTANT SURGEON GEORGE ARTHUR detached from the U. S. S. Vandalia and ordered to Naval Hospital, Norfolk, Va.

ASSISTANT SURGEON S. H. DICKSON detached from the Naval Hospital, Norfolk, and waiting orders.

BOOKS AND PAMPHLETS RECEIVED.—The Sanitation of Small Cities. By David Prince, M. D. (Reprint.)

Lectures.

CLINICAL LECTURES ON ORTHOPÆDIC SURGERY.¹

DELIVERED AT BELLEVUE HOSPITAL, NEW YORK.

BY LEWIS A. SAYRE, M. D.,

Professor of Orthopædic Surgery and Clinical Surgery in Bellevue Hospital Medical College.

II. POTT'S DISEASE OF THE SPINE. (CONTINUED.)

GENTLEMEN, — I have already lectured so much on the subject of Pott's disease that there would seem to be but little left for me to say in regard to it; but during the last few days several cases of the affection have come under my notice which have been receiving other forms of treatment than that which you have been accustomed to hear me advocate, and I have therefore thought it well to bring some of them before you, in order that you may be better able to appreciate the advantages of that by partial suspension and the use of the plaster-of-Paris jacket over every other that has as yet been devised. Other cases have also come into my hands of late in which the treatment by suspension and the plaster jacket has been improperly managed, and from these I desire to impress upon you in the most forcible manner that I am capable of a most useful lesson, namely, the importance of attention to all the details that have been prescribed in the method. In illustration of this point I will show you two cases which have been treated by means of the plaster jacket, and yet treated in the worst possible manner, the results being as unsatisfactory as if the patient had been treated by any of the methods formerly in vogue, and still practiced by some, though they now stand condemned in the light of modern surgical science.

The plaster jacket can do just as much harm as these in the hands of the ignorant or careless; for it is not so much upon the dressing itself as on the proper manner of applying it that success depends in any instance. After an experience now embracing many hundreds of cases, I can confidently and positively assert that if this plan of treatment is carried out just as it should be the patient suffers *no pain whatever*. Whenever in any case pain is complained of, you can rest assured that some mistake has been made in the application of the dressing, and it at once becomes the duty of the surgeon to remove it entirely and find out what was wrong about it.

CASE I. Our first patient to-day is a little fellow whom you will probably all remember as having been brought here a few weeks ago by Prof. Alfred C. Post. The child had had Pott's disease for two years, and for nine months before Dr. Post saw him had been under treatment at the Hospital for Ruptured and Crippled in this city. In consequence of the pressure of the iron cross-bar of the instrument which was ordered to be worn by the surgeon in attendance, an enormous lumbar abscess was formed, and this you will remember was operated upon by Dr. Post in the most brilliantly successful manner by Callender's method of hyperdistention of the sac. When first shown you, before the application of the plaster jacket, the little patient could not stand, except by resting his hands upon his thighs, as seen in photograph. He had also the peculiar grunt which is so characteristic of these cases.

Immediately after the lecture the plaster dressing was put on, and, on account of the high point at which

the disease was situated in the vertebral column, it was found necessary to employ the head-rest in addition. The child has worn the apparatus ever since, and there has already been very marked improvement, so that now, as you perceive, he walks as erect as a drum major. Such a practical illustration renders it quite unnecessary, I think, to dilate much upon the advantages of this method of treatment. To be convinced of the benefit that has resulted from it here you have but to look at the rosy hue upon the cheek that has replaced the sickly pallor which you saw before and which belongs to all cases of Pott's disease, and to contrast the smile of contentment on the little one's face with the pinched and anxious expression which it habitually wore previously. [See photograph.]

CASE II. I come next to the cases of which I spoke as showing the bad results of this same method of treatment when improperly applied. The child now before you was suffering from Pott's disease, and the physician in attendance concluded very properly that the best way of treating it was by means of the plaster jacket. Unfortunately, however, either through ignorance or carelessness, he neglected to attend to all the minute details of the application, which may at first sight seem of but little consequence, but which I have always insisted upon as of the greatest importance in order to secure the perfect success which is attainable by the method. So, instead of first putting on a knit shirt made exactly to fit the patient, he used no shirt at all, but applied the plaster bandage directly upon the skin itself. In order to prevent pressure upon the spinous processes of the affected vertebrae he placed several strips of green pasteboard on either side of them before putting on the dressing.

After the application the child became so comfortable that both the physician and the parents were delighted. In about three weeks, however, the child began to complain of pain; but the doctor, because the jacket had afforded relief at first, refused to remove it. Consequently, as the pain and discomfort continued to increase, the mother took the dressing off herself, when she found that the green poisonous pasteboard had been reduced to a pulp by the perspiration, and had fallen down over the hump, and that a large slough over the seat of disease had been caused by its pressure. So the mother and the doctor were now as much disgusted as they had at first been delighted with the plaster-of-Paris treatment.

The patient was then brought to New York, and after he had worn iron braces until he became paralyzed the mother came to consult me. The child was then in a terrible condition, as, in addition to the paralysis, there was an ulcer two inches in diameter over the diseased vertebrae sloughing down to the bone, and another one of rather less size over the sacrum. On account of these circumstances I had to put on two or three plaster jackets before I succeeded in getting one that was quite satisfactory and rendered him perfectly comfortable; but I persevered until this had been accomplished, and that was the end of the story. He is now so near complete recovery that you can hardly form any idea of what a bad way he was in; but when I remove the dressing you can still see cicatrices of the enormous ulcers of which I have just spoken. The last jacket, which he is still wearing, was put on five months ago, while I was in Europe, by my son, a hole being cut in the plaster over the seat of disease. In a few weeks afterward the jacket was cut

¹ Reported for the JOURNAL.

down in front, and its edges were provided with eye-lets, so that it could be laced up like a corset. The child can now walk about with perfect freedom, and can jump, as you see, heavily upon the heels, without the slightest inconvenience, when the jacket is off, so that we can regard him at the present time as practically well. He can continue, however, to wear the jacket as a corset, as a means of protection against relapse.

CASE III. I now have to show you a case in which the plaster treatment, and every other in fact, was abandoned as hopeless by those who previously treated him. There was a projecting point over the sternum as well as in the back, as is frequently the case in Pott's disease, and as pressure was not guarded against in the application of the dressing employed the most serious consequences have resulted. If cartilage once begins to slough, the process is an extremely tedious one, lasting much longer than caries in bone. In applying the plaster dressing in cases of this kind we should not only protect such projecting points by pads on either side of them, but also cut out holes of sufficiently large size over them in the jacket after it has been completed.

We are now ready to put on the plaster before you, and as this is being done I beg that you will once more notice carefully all the minutiae of the process, which I have in former lectures fully described to you, and which it will scarcely be necessary for me to mention in detail on this occasion. In order to have the tight-fitting knit shirt entirely without wrinkles during the application of the plaster, the front and back of the garment should be pinned together between the legs, and a safety pin should always be used for this purpose. This may seem a trifling point; but if the pin should happen to prick the child while the dressing is being put on, it might kick and struggle in such a manner as to render it necessary to do the whole thing over again. Before suspending the child I take it across my lap (which puts it in a perfectly comfortable position, because it relieves all the pressure upon the diseased part), and place a pad upon each side of the affected vertebra, parallel with the spinal column. We then put him in the suspensory apparatus, and having raised him until this position of perfect comfort is reached, two similar pads are placed on either side of the projection on the sternum, when the application of the plaster bandage is commenced. This child was brought to me two days ago from Maine, wearing a plaster jacket, it is true, but suffering the most intense agony, because little or no care had been taken to protect these exposed points from pressure. The casing was about an inch in thickness, and the mother stated that the physician who had put it on, instead of carrying the suspension *just to the point of comfort*, raised the child until its feet were two or three feet from the floor, where it was left dangling about, with no assistant to steady it, all the time that the dressing was being put on.

When the disease is as high up in the spinal column as in this case, it is necessary to resort to the "jury mast," or head-rest, in addition to the plaster jacket. After a few turns of the plaster bandage have been made around the trunk, this apparatus—the "jury mast"—is placed in position, and then secured by applying the bandage over the iron frame behind and the strips of perforated tin passing around to the front of the thorax. The application is then continued, layer by layer, until the complete jacket is formed; and when this is done we must not forget to press the casing close into the iliac fossæ, which flattens it out, and

thus prevents undue pressure upon the anterior superior spinous processes of the ilia. I think you will all now be struck with the difference in the color of the child's face since the jacket has been put on. Previously, as you must have noticed, it was excessively pale, but now already the cheeks have assumed a rosy hue. This is due to the more free oxygenation of the blood, which I believe to be one of the most important features of this treatment. On account of the conical shape of the trunk and the close manner in which all its interstices are filled by the dressing, the spine is rendered straight and immovable; while, on account of the pad which is placed on the anterior portion of the chest and the abdomen previous to the application of the plaster, as well as the flattening out of the casing over the projecting points of the ilia, there is not only no interference whatever with the organs of respiration and digestion, but they are enabled by means of it to perform their functions in a more perfect manner than would be otherwise possible.

At this point I wish to direct your attention for a few minutes to the contrast as regards respiration between the plaster jacket and the Knight apparatus, such as I hold in my hand, or any other which consists of iron bars applied to the back and held in position by means of a canvas webbing that laces tightly across the chest in front. It is altogether impossible to construct an apparatus of this character which will fit the thorax accurately, and while the organs of respiration are compressed by the tight lacing over them there are spaces left at the back and sides (just where it is most important) where no support at all is afforded. I have taken off numbers of these "cribs," as I sometimes call them, from patients who have been under treatment at the Hospital for Ruptured and Crippled, and I have yet to meet with the first case in which no galling or chafing was occasioned by the instrument.

CASE IV. The next case illustrates several of the points to which I have alluded in my remarks to-day, and as it is a very interesting one I will give you the history somewhat in detail, as it is recorded in my books. The patient, whose name is Louis E—, first came under my notice six months ago, when he was six years old. The parents and one other child are healthy. He enjoyed good health up to September, 1877, when he fell down a flight of four stone steps and struck upon his back and head. About a month later it was noticed that when he walked his body inclined towards the right, and he was taken to the family physician, who told the parents that he thought there was something wrong about the spine (though there was no deformity), and recommended a spinal brace. This was applied by the instrument maker who manufactured it, and was worn by the child for three months. About three weeks after the apparatus was applied, a projection was discovered on the spine, about the upper and middle dorsal vertebra, and after this he steadily grew worse. At the end of the three months he was taken to a hospital especially devoted to the correction of this class of deformities, where one of the usual braces used in that institution was applied on the 13th day of May, 1878. From that date to the time when he first came under observation the mother says he had worn no less than seven of these instruments. During this period, she further says, the deformity did not increase very much, but the child suffered a great deal of pain.

When the instrument which he was wearing at the time was removed at my office, it was found that the skin was chafed on each side of the spine from the pressure of the iron rods in this position, and also over the shoulders and ilia from the pressure of other portions of the brace. The patient was wholly unable to stand erect, even while wearing it, and he was constantly obliged to support the trunk by means of the hands placed on the thighs.

The child was suspended, and a thoroughly-fitting plaster jacket with head-rest was applied, when he immediately became perfectly comfortable, and as soon as the plaster had set was able to stand up straight without any other support whatever. Since then two more jackets have been applied, and the child has continued to do perfectly well until very recently, when he has complained of some pain over the seat of the disease. This was because the jacket had become too tight for him, on account of his rapid growth, and when he was brought to my office to-day I therefore cut it down the centre, as you see. The moment that we remove it now he feels the need of it, and cannot stand with comfort without supporting the trunk by resting his hands on his thighs. Yet there has been very marked improvement since he came under treatment six months ago. At that time there were excoriations not only over the anterior superior spinous processes, but also over the posterior crests, of the ilia, as well as all other prominent bony projections, which had been produced by the instrument that the child had been wearing. But this was not all. On either side of the spine at the seat of disease, extending for a distance of at least two inches, there were other excoriations, which were the result of the pressure of the two upright iron bars of the brace; and the cicatrices of all these sores are still plainly visible, as I now point out to you. Yet for months and months this little patient was compelled to wear this instrument of torture, and suffer untold agonies,—and all in the name of science and humanity, forsooth! Such cruelty is so barbarous in its character, and so totally unnecessary, that it seems to me that it is time that it should be put a stop to by the strong arm of the law. If the lower animals are so zealously and vigilantly protected from injury by Mr. Bergh's society, certainly the association which has for its object the prevention of cruelty to children should not be any less efficient; and here, I think, is a fair field in which it may legitimately carry out its benevolent work. Such unscientific treatment, which inflicts so much unnecessary pain, in the very face of recent developments of methods that are far superior in their results and entirely painless in application, is not creditable to our profession.

As it is desirable that the boy should have a clean knit shirt before the jacket is reapplied to remain, I will to-day simply make a few turns of the plaster bandage around the old one, to secure it in position temporarily, after having put in sufficient padding in front to separate the cut edges to such an extent that the dressing will no longer be too tight for him. At once, you see, he is able to stand perfectly erect and walk about with ease; and I want you to contrast his present appearance and carriage with what they were six months ago, as exhibited in this photograph which I now show you. When it was taken he was making his best effort to stand up straight; but in spite of this you see that his body was bent over at an angle of about forty-five degrees, and that even thus he was compelled to rest his hand upon his thighs.

[The next day a new knit shirt having been put on him, Dr. Sayre reapplied the old jacket, which had been cut down in front, as it was perfectly fitted to the surface of the trunk. Before doing so, however, he removed the outer layers of the dressing down to the head-rest apparatus, and put in enough padding in front to separate the edges of the carcass nearly an inch, so that there should be no undue compression. The "jury mast" was then secured in position again by a fresh plaster bandage, enough layers of which were put on to make the whole jacket perfectly compact and firm. When this was completed, the child felt entirely comfortable, and was able not only to walk but to run without support.]

CASE V. In order to remind you of a still further application of the plaster jacket in spinal troubles, I now again introduce to you with great pleasure my friend, Dr. C. W. Hackett, of Massachusetts, who you will no doubt remember first came before you six weeks ago to-day. Two years ago last October he was unfortunate enough to receive a fracture of the lumbar vertebra from a railroad injury,¹ which resulted in paralysis of the bladder, rectum, and lower extremities, as well as the formation of numerous abscesses. Up to six weeks ago last Sunday he had not been able to walk a single step, or even to stand without powerful support. On that day his spine was extended by

¹ [At the request of many professional and other friends, Dr. Hackett has sent us the following statement for publication.—ED.]

RAILROAD INJURY. CASE OF DR. C. W. HACKETT.

October 15, 1877, in switching from a main track to a branch, the train going round a curve at a rapid rate, while I was standing in the rear of the car, I was violently thrown upon the corner of a stove, and instantly paralyzed below the waist, probably by a fracture of one of the lumbar vertebrae,—presumably the third. While paralysis of motion was complete at the time, there was some sensation and pain in the outside of the left thigh for a few hours. There was loss of control of the bladder and rectum, with a feeling of constriction, as of a tight band, about the lower part of the abdomen, the line of demarcation between the active and paralyzed parts being clearly defined. Pain at the point of injury was incessant, and severe beyond description. The bowels were evacuated by cathartics and clysters, and the bladder by the catheter, with treatment expectant only. After ten weeks there was some return of sensation, with ability to evacuate the bladder voluntarily as a general thing, and in a little more than five months from the time of the injury there commenced a slight muscular action in the legs, which increased irregularly, so that in a year after the hurt the limbs could be drawn up and pushed down in the bed, and even be made to move as in walking, with the body supported on crutches and by an attendant; but only a trifling amount of weight could be sustained by them.

During all this time there were frequent periods of almost total paralysis of both motion and sensation, greatly influenced, evidently, by the action of numerous abscesses, which began about six months after the injury, discharging through the rectum, the outside of the right thigh, and the inside of the left,—the latter giving exit to two fragments of bone half an inch to an inch or more in length, and from one to two lines in thickness: one piece from two to three lines in width at the base, tapering to a point, and partly necrosed; the other, from one to two lines wide, somewhat pointed and slightly curved or twisted in shape, but perfectly bright and clean, and showing its fracture very plainly. I am confident that another fragment of bone had previously escaped per rectum, while still another was distinctly felt in the abscess that formed in the outside of the right thigh, but afterwards disappeared. During the winter of 1878-79 abscesses formed with great frequency, causing much loss of strength through the large quantities of pus formed and the pain they entailed; the partial recovery from the action of the muscles was in a great measure lost, so that they responded to the test of electricity no more than would those of a man recently deceased, and I was unable to distinguish the difference between heat and cold when applied to the surface of the extremities,—indeed, so imperfect was sensation that I had both legs badly burned on different occasions by hot soap-suds without being aware of it at the time (it here occurred to me to use artificial heat to maintain proper warmth in the extremities).

The abscesses finally stopped forming under the use of iodide of potassium, so that after May, 1879, only two appeared,—the last about the first of August. With the cessation of abscesses improvement took place in the general health and in the action of the legs, apparently aided by the daily use of electricity and frictions, and

suspension and a plaster jacket applied, and on the ninth day afterward he actually walked from his boarding-place on Lexington Avenue to my office, a distance of fully half a mile, and ascended a long spiral staircase at the end of it. Dr. Hackett, I am happy to say, has recently written out a detailed account of his case, which I am sure will be read with great interest by all the profession. [See foot-note.]

The great difficulty in applying the plaster jacket in this case was to get a proper support for it over the hips, because the doctor, from his long inactivity, had grown so stout that they did not project, as is ordinarily the case. On account of his great muscular power in his arms, however, he was able to remain suspended until the dressing had been molded as well as possible into the intercostal spaces and the iliac fossa and the plaster had become perfectly set. If we had attempted to lay him down as soon as the jacket was put on, as is usually done, I think it altogether probable that it would have been cracked, and the whole thing would have had to be gone over again. Ever since then he has been able to walk about with comfort, and has improved steadily in every way. For a considerable

the persistent exercise of the muscles by volition; so that by the autumn of 1879 I was able, at times, to get a part of my weight on my feet by supporting myself on crutches or over the back of a chair. But I was still unable to be off my bed, except for a short time during the day, and often did not even make the pretense of sitting up for more than a week at a time; was compelled to evacuate the bowels by injections, except at times when suffering from painful diarrhoea; and was suffering intense pain in my spine and limbs all the time, which compelled me to take from one to three grains of morphia daily to keep even bearably comfortable.

On November 30, 1879, the actual cautery having previously been applied with but trifling benefit, if any, I was suspended and encased in a plaster-of-Paris jacket by Prof. Lewis A. Sayre and his son, L. H. Sayre, of New York, assisted by other members of the profession in that city and from Massachusetts, the relief from pain and the improvement in the sensation and motion of the limbs produced by extension indicating the probability of benefit by this mode of treatment. The jacket was applied in exactly the manner so clearly set forth by Professor Sayre in his valuable work on Spinal Disease and Spinal Curvature, etc., the closest attention being given to the minutest details of the operation from beginning to end, and the result was a remarkably accurately fitting case, which gave perfect and even support to the whole trunk, and complete and absolute rest to the injured and diseased parts. Three days after being "turtle-helled" I could walk about the room without mechanical support, and two days later I went out on the street for my first walk for more than two years. Sensation, which had been very imperfect, became nearly normal; control of the muscles became constant and much more perfect; the frequent attacks of spasmodic contractions of groups of muscles entirely ceased, as did also the occurrences of almost total paralysis of the legs, during which I would often be unable to draw them up in bed for days at a time; complete control of the bladder was obtained, and the bowels became much more normal in their action, enabling me wholly to do away with the use of injections, which I had almost invariably been compelled to resort to before to produce evacuations. I was also able to discontinue the use of heat to the limbs, they being as warm as other parts of the body.

Though still suffering severe pain at the point of injury, I have succeeded in reducing the quantity of morphia to less than one half of that taken before the jacket was applied, and that in a period of six weeks' time. The muscles are still too weak to sustain the weight of the body with the legs flexed, or to raise it on the ball of the foot and propel it forward, as in natural locomotion, thus giving me a necessarily slow and somewhat awkward movement; but there appears to be paralysis of no muscle now, and I am able to walk a fourth of a mile without artificial aid of any kind, except the moral support of a light bamboo cane.

On removing the jacket, January 13th, I found myself unable to walk across the room without support of some kind, while there was a marked increase of pain. There was also a perceptible change in the form of the trunk, it being two inches smaller around the waist, probably by absorption from lateral pressure of the jacket above the ilia, where it had been crowded in to get a point of support to maintain extension. Upon the application of a new plaster case there was immediate relief of the increased pain and return of the use of the legs as before, with considerable improvement in their action (the new jacket being a better fit than the first, if possible), showing more clearly the need of case the greater the relief from the extension and support of the plaster-of-Paris jacket.

February 1st. I can now raise myself on the toes by voluntary contraction of the extensor muscles of the feet. — C. W. H.

time now he has been absent from the city, but yesterday he returned and told me that he had not felt quite so well of late, as the jacket had begun to slip up and down to some extent. This would not have occurred but for the difficulty of which I told you in getting sufficient support for the dressing from the hips, and there will be no trouble of this kind in the future, for the doctor having now for some weeks been able to take a considerable amount of exercise, his trunk has in a great degree resumed its natural proportions, and will easily retain the jacket in its proper position. When he came to me yesterday I cut down in front the jacket applied six weeks ago, and took off about an inch of it on each side. It was then reapplied and secured in position by a firm bandage, but in order that there might be no compression of the organs of respiration or too much pressure over the hips, considerable padding was previously put in the upper and lower portions of the jacket. It will thus be seen that around the waist, where the shrinkage had taken place, the jacket was some two inches smaller in circumference than before. Still, the doctor tells me that he does not feel altogether comfortable, although the alteration thus made is a great improvement. In a day or two, therefore, I will put on him an entirely new jacket, and in the course of the next few weeks I have no doubt that he will be so far improved that this may be cut down in the centre and provided with lacing like a corset, so that it can be removed at will. In conclusion, I do not hesitate to say that in Dr. Hackett's case we have one of the most remarkable instances of the advantages of the plaster-of-Paris jacket (applied during the suspension of the patient), in injuries and diseases of the spine that the history of surgery has yet recorded.

[Four days later Dr. Hackett called at Dr. Sayre's office, and the old jacket was removed entirely, when it was found that he was unable to walk at all. By direction of Dr. Sayre he ate a hearty meal so as to distend the stomach as much as possible, and after putting on a fresh skin-fitting knit shirt, suspended himself while a new jacket was applied, under "dinner-pad" being used in this instance. On account of the great muscular development of his arms, he was able to keep him self-suspended in the apparatus for no less than forty minutes, during which time the plaster had become rather firmly set. He was then seated on a stool placed under him, in which position he kept himself partially suspended for nearly an hour, during which time the plaster had become thoroughly "set." When he got up he expressed himself as feeling more thoroughly supported than ever before, and as entirely free from pain, while he was able to walk with the greatest ease.]

THE HAYDEN CASE.

BY GEORGE JEWETT, M. D., FITCHBURG.

MAY 2, 1879, at 8.30 P. M., I was summoned to attend Miss Sarah E. Hayden, a single lady of thirty-eight years, a school-teacher of Fitchburg. She was in bed, was lying partly upon her right side and back, the lower limbs slightly flexed, her position being one of ease and repose. Her face was calm and pallid, with a dark shade under both eyes. There

was no restlessness or other indication of suffering. Her intellect was clear, mind undisturbed; and although not inclined to talk freely, yet she answered readily and concisely questions relating to her condition. She stated that she was not in pain; made no complaint of disturbed sensations in any part of her body, except nausea. Pulse 80; in right wrist markedly weak, so much so that I tried the left, and to my surprise found the pulse almost entirely wanting. Respiration was normal in frequency; no cough, nor rales in chest observed. The surface of the body was cool, slightly moist, and very pale; feet and lower limbs cooler than other portions. Near the head of the bed was a vessel containing about a pint of a greenish fluid, a large portion of which seemed to be mucus, which I learned she had vomited about half an hour before my visit. Upon inquiry and subsequent investigation, the following history of the case was obtained; very few of the facts, however, were made known to me at my first visit. Both her father and mother had recently died after short and unusual illnesses, which fact had somewhat depressed her, but aside from this natural cause she was in her ordinary health at ten o'clock, p. m., May 1st, except a slight pain in the muscles of the neck and back, which had troubled her for a few days. At this time her brother induced her to use a liniment for the pain in her neck, and to take a cachet of soda "to settle her stomach." Miss Hayden and a lady friend now retired, and both were soon asleep. At twelve she woke her friend, exclaiming, "I feel dreadfully! Rub me." She said that she had a "creeping sensation all over, as though her blood did not circulate." The brother soon came to her assistance, giving her, as he stated, Jamaica ginger, and subsequently some peppermint. After friction of the back and limbs, she soon fell asleep. At five a. m. she awoke with dizziness, nausea, and depression. At seven the brother gave a cachet of mustard, as he said; an hour or more afterward mustard was given, at her request, in water, to relieve the nausea, which was quickly followed by the ejection of about a pint of fluid, in which was an undissolved cachet, a piece of pickle taken at her dinner the previous day, and a few spiced currants, eaten with her supper. From this time until noon she remained in bed, with no marked symptoms except nausea and depression, when, with some assistance, she dressed, went downstairs, and her brother gave her some tea. At three o'clock the same person gave a teaspoonful of calcined magnesia in milk, soon after which she vomited a greenish fluid. Some gruel now taken remained on the stomach. At 5.15 more magnesia was administered, when, tired and faint, she went to her room and to bed. An hour later she had an abundant discharge of a thin brownish substance, in which were undigested currants. This discharge was accompanied by pain, faintness, and great prostration. Half an hour after this was another discharge, of the same character, small, and without pain or marked faintness. At my visit, this part of the history was not mentioned. About this time she failed in an attempt at micturition, which subsequently was both painful and difficult. At 7.15 she took from the same hand more magnesia. She now became tranquil, and remained so until my visit, with the exception of a single act of vomiting without marked distress. At 8.30 the salient points were, slight nausea, failure of the heart's action, notable absence of pulse in left wrist, and marked and progressive decrease of temperature. There was and had been entire absence of thirst, pain-

ful or difficult deglutition, heat in throat, pain or tenderness at epigastrium. The greenish mucous ejection indicated gastric irritation, for which, as a curative agent, I administered from my pocket-case subnitrate of bismuth, directing it to be given in two-grain doses every fifteen minutes while the nausea continued. I also ordered mustard to the epigastrium, general artificial warmth, and stimulants as they could be tolerated. I directed great watchfulness, and that I should be called at any unfavorable change. I left at nine o'clock.

At twelve a messenger came, stating that my patient seemed to be dying. I requested him to call to my aid Drs. Colony and Thompson. The patient being quite near my home, I was soon at her bed-side. She was feebly tossing her head and shoulders from side to side, struggling as if in the act of suffocation. She was perfectly intelligent; said she had no pain, but could not breathe. Her pupils were completely dilated; she was pulseless, and evidently dying. I gave her some undiluted whiskey, which she swallowed without difficulty; but the power to swallow quickly ceased, and with the concurrence of my associates, who had now arrived, I continued it by subcutaneous injection. In a few minutes the heart's action ceased. As no satisfactory diagnosis could be made by myself or conferees, and suspicious circumstances indicating death by poisoning came to light, an autopsy was held by Medical Examiner Dr. E. P. Miller of Fitchburg, with the following result:—

Autopsy thirty-two and a half hours after death. Rigor mortis well marked; no unusual appearances on surface of body. The abdominal cavity being exposed, the stomach and two or three feet of intestine adjoining were of a bluish color; other portions were pale. The stomach was carefully removed, and its contents, which consisted of about ten ounces of a thin brownish fluid, were emptied into a jar. Its entire mucous surface was of a reddish-brown color, with patches and points of bright red, most abundant near the pylorus, indicating hemorrhage into the mucous membrane; numerous minute white specks were also observed on its walls. On opening the intestines, the whole surface of the upper portion was found much redder than normal, while on the upper part of the duodenum, near the pylorus, was a very bright patch of red. The liver was darker and more full of blood than usual, no signs of disease observed; right kidney of a dark bluish color, and much congested; left kidney the same, except that under capsule was an exudation of fluid blood; nothing unusual seen about the spleen, pancreas, or other abdominal organs worthy of note. The heart, and all large blood-vessels were filled with bluish-black fluid blood; otherwise their condition was normal; no clots discovered in whole body. Lungs moderately collapsed; color, externally, darker and bluer than natural, and crepitation everywhere; on section an unusually large amount of bluish-black blood flowed out, especially in lower lobes. Cadaveric odor was entirely wanting. On removal of calvarium and dura mater the arachnoid in dependent parts bulged from accumulated serum underneath, from which, when cut, an ounce or more escaped; all the small vessels on the surface of the brain were full of bright red blood; parenchyma more moist than natural; no fluid in ventricles or other abnormal change noticed.

The stomach and contents, portions of liver, intestines, and brain, were sent to Dr. William B. Hills,

assistant professor of chemistry in Harvard Medical College, for chemical analysis, and also a sample of the bismuth from which that given the patient was taken. Subjoined is Dr. Hills' report. It is proper here to state that the counsel for the defense attempted to show that the arsenic found in the organs submitted for analysis was given by the attending physician, either by mistake or in the bismuth administered at his first visit, as it is a recognized fact that commercial bismuth is generally contaminated by arsenic:—

"May 5, 1879. Received from Medical Examiner Dr. E. P. Miller stomach and contents (contents measured ten and one third fluid ounces); intestines and contents (contents measured five and five sixths fluid ounces); portions of liver and brain; mucous membrane of small intestines, very much inflamed in its upper part, beginning at the stomach, extending downward twelve to fifteen inches; for the remainder of its length normal.

"Scattered over the inflamed portions of the mucous membrane was a white gritty powder, shown by analysis to be white arsenic; 1.14 grains of the solid were recovered. Contents of the stomach were a dark, viscid mucus, and contained a considerable quantity of bismuth subnitrate. Numerous crystals of white arsenic were also detected by the microscope. Amount of white arsenic in contents of stomach was .578 grains; in contents of intestines in solution 2.72 grains; and 1.14 grains solid, removed. Amount of arsenic in liver, 2.77 grains. Total, 12.41 grains. There was fatty degeneration of the liver shown by the microscope. Brain contained a trace of arsenic. The bismuth received from Medical Examiner Miller was unusually pure, containing less than one tenth of one per cent. estimated as white arsenic, and it would have taken about 27 ounces of this bismuth to have contained the amount of arsenic found in the organs. Bismuth never contains crystals of white arsenic as an impurity. A sample of magnesia from that given the patient was found free from arsenic."¹

The pathology of arsenical poisoning opens a wide field for investigation. From the books little can be learned of the effects of arsenic upon the living tissues, or of the manner in which it causes death. We know it is hostile to all forms of organic life; that when absorbed it is carried to all parts of the system by the blood, and is deposited in various organs by choice, the law of election of tissue being as yet unknown. I am not aware that it has ever been detected in the lungs, not even a trace. It seems to be found in the greatest abundance in the liver, nervous centres, kidneys, spleen, pancreas, and in more minute quantities in the muscular and other tissues.

Prof. E. S. Wood says: "Some experiments upon animals appear to point to a deposition of arsenic in the brain and spinal cord, and it is stated that the accumulation in the nerve tissue takes place before that in the liver and kidneys; but I cannot learn that any analyses in the human subject confirm these experiments upon animals, or that anything definite is known of the rapidity or amount of its deposition in the human brain."

Taylor states that its deposition in the liver reaches its maximum in fifteen hours, and in all cases, if life is sufficiently prolonged, it entirely disappears by elimination.

¹ Portions of the various organs were given by Dr. Hills to Prof. Edward S. Wood, of Harvard Medical College, for analysis, who verified both the results and estimates to within a hundredth of a grain in the aggregate.

This process of absorption is supposed to be completed often in a few hours, as numerous cases of arsenical poisoning have been reported in which no trace of arsenic could be found in the body after death.

In some instances this poison seems to act primarily upon the nervous system. Stillé states that nine men swept up some arsenic scattered in the hold of a ship. Of these several were suddenly seized with vertigo, and fell senseless. Subsequently they were attacked with vomiting and other symptoms of arsenical poisoning, of which three died.

Of the pathological changes observed no one is more constant than acute fatty degeneration of the liver. Dr. William B. Hills reports three or four cases under his own observation, in all of which it was markedly present. In support of this statement we have such eminent authorities as H. C. Wood, Virchow, Rindfleisch, Casper, Hoffman, Tardieu, Orth, Wagner, and many others. From our present knowledge the kidneys seem to be the principal if not the only source by which arsenic is eliminated from the body. It is uniformly found in the urine soon after its absorption into the circulation, and continues to be detected so long as any remains in the system during life. Perhaps the most striking element in arsenical poisoning is the absence of uniformity in the symptoms. The eminent toxicologist, Tardieu, groups them into four classes:—

"First. A sensation of heat and nausea; abundant and repeated vomiting; ardent thirst; drinking increases vomiting; pain in epigastrium, increased by pressure; sometimes violent pain in head; altered features; coldness of extremities; extreme weakness; tendency to faintness; smallness of pulse; evacuation of the bowels, with vomiting, discharge sometimes involuntary; painful cramps in limbs. Face, first pale, becomes bluish. Skin cold. All excretions stopped. Death comes on in twelve, fifteen, or twenty hours from first symptom.

"Second. Rare cases in which there is no vomiting nor evacuation; pulse tranquil; marked calmness; faintings, sometimes followed by coma. Death without pain in from five to twenty hours.

"Third. Subacute and most common. Vomiting abundant and repeated at beginning, which ceases after one or two days, and with disappearance comes amelioration of symptoms; stomach indolent; tongue natural; heat in throat; thirst and general coldness continue, also great weakness and irregularity of pulse; suppression of urine; spasm of throat; painful swallowing. Sometimes reaction comes on. The belly is tender, hard, and swollen. Fever lights up. Pulse frequent and strong. Sleeplessness, agitation, and spasmodic movements; eruptions on the skin; intelligence undisturbed. Later, pulse fails, is more frequent and feeble; obscurity of the senses; cold extremities, and death in from two to six or ten days. Sometimes recovery."

Taylor says,¹ "The symptoms do not appear to bear any relation to the quantity of poison or the form in which it is administered. Those indications of irritation in the stomach and bowels, or of an affection of the brain, have equally occurred whether the dose was small or large, or whether the poison was in a state of powder or solution. The variableness is also observed in regard to the time intervening between taking the poison and the first symptoms." In proof I will cite

² Taylor on Poisons, page 326.

the following cases: ¹ A young man accidentally took a large dose mixed with his food. Death occurred in twenty minutes from his sitting down to his meal. McCauly reports ² the following: A man took one hundred and fifty grains of arsenic. No symptoms for six hours; then vomiting, purging, and drowsiness set in. No pain or tenderness of abdomen. Death (time not stated). Mr. Todd reports ³ a case where sixty grains were taken on an empty stomach. No symptoms for two hours. Dr. Leachese ⁴ reports a case where a large dose was taken. No symptoms for seven hours. Dr. Thompson, of Liverpool, Eng., reports a case where thirty or forty grains were taken; no symptoms for five or six hours. Taylor reports a case; no symptoms for ten hours. Mr. Clegg reports a case where no violent symptoms appeared for twenty-three hours; then death in half an hour. The patient was sick one half an hour after poison was taken; then narcotism and death in twenty-three hours. Tonellier reports that a female took a fatal dose; no symptoms for eight hours. Dr. Bryon ⁵ gives a case where no active symptoms were manifest for nine hours. Orfila ⁶ reports a case; no symptoms for seven hours.

In the case of Francis E. Hayden, on trial for the murder of his sister, the government assumed that arsenic was given in the cachet at ten o'clock, May 1st. If so, the first symptoms, which were of general distress, occurred in two hours; the accompanying hyperæsthesia would indicate a shock to the nervous centres, which might have been allayed by a large dose of morphia given in the tincture of ginger or peppermint.

Sleep sometimes follows the administration of arsenic. A case is reported ⁷ in which an adult male took thirty grains, slept nine hours, then vomited, and death occurred in three days. Another case is reported ⁸ where a female took two and one half grains at bed-time; had a restless night; death came in thirty-six hours. McCauly reports the case of a man who took four hundred and twenty grains of arsenic; slept three hours, when symptoms set in, with death in nine hours. Cases are not wanting in which none of the ordinary symptoms of arsenical poisoning are present. Dr. Morehead reports ⁹ a case of death by narcotism in which arsenical poisoning was not suspected. An autopsy revealed a large amount of arsenic in the stomach. Dr. Todd, of Providence, relates the case of a child who was observed in the act of eating some arsenical paste, prepared for poisoning mice. An emetic was given; between the acts of vomiting the child was lively, with no symptoms. It soon slept with the calm of health; then had two natural discharges. In six or seven hours there was no expression of pain. Soon the surface of the body became cool; lips livid; eyes sunken, pupils fixed and dilated; pulse scarcely perceptible; respiration sighing and feeble. Death eight hours after taking the poison. An inspection of the body after death revealed no change from a healthy condition. A little mucus was found in the stomach, but there were no signs of inflammation. Dr. Alexander ¹⁰ took by mistake a large

quantity in some gruel, and died on the sixteenth day. No arsenic was found in the body. Sir Robert Christison relates ¹¹ the case of a lad of seventeen, who, after a night's debauch, swallowed half an ounce of arsenic. In two and a half hours there were no symptoms except languor and drowsiness. In eighteen hours he began to sink, and then presented the usual constitutional symptoms of arsenical poisoning, and died in forty-one hours, with scarcely a single local symptom excepting slight vomiting. The stomach was violently inflamed. Dr. Stillé reports ¹² that a woman took three hundred grains of arsenic after a hearty meal. No medical treatment for one and a half hours, or vomiting, yet she completely recovered in five days. Dr. Jackson says ¹³ a man took not less than two ounces of arsenic on an empty stomach. The greater part was retained for six hours; then great irritability of stomach, but final recovery.

From all the facts in my knowledge, I have no doubt that a dose of twenty grains or more of arsenic was given May 1st, at ten o'clock, p. m. in a cachet. The following morning a second cachet was given, not of mustard just prepared, as stated by the accused, but containing something else, prepared the day before. Almost daily experience shows that the two halves of a freshly prepared cachet separate in a few moments, when placed in water, and float from each other, but when prepared with considerable moisture, and allowed to dry before taken, the margin dissolves very slowly. This cachet was retained on the stomach from one to two hours, when it was ejected *whole*. This incident led me to experiment upon the composition and administration of cachets. I find that they are composed almost entirely of starch; are not affected materially by artificial digesting fluids at the temperature of the blood; soften readily in any fluid, dissolve very slowly in water, and are comparatively insoluble in a solution of arsenic; digested sixty hours, in such a solution at blood heat, are little changed, and retain their form for a month in a similar solution at ordinary temperatures. This fact helps us to account for the condition of things when the cachet of the morning was ejected, and the inference plainly points to the conclusion that this cachet had been immersed in a solution of arsenic then existing in the stomach. Extending my experiments, I gave a dyspeptic person a drachm of pulverized ipecacuanha in three medium-sized cachets at twelve o'clock, on an empty stomach: at 12.30 no nausea. I gave fifteen grains sulphate of zinc in cachet, followed by a few ounces of warm water: 12.40, unusual motion of stomach and eructation; 12.45, vomiting of a few ounces of watery fluid; 12.50, copious emesis of a mucous watery fluid, containing flocculent masses of broken-down cachets, mixed with ipecacuanha. The patient stated that ejected matters were bitter and "puckery;" no discomfort for thirty minutes, when he suddenly ejected fluids of similar character tinged with bile; no further nausea. His appetite returned, and he was immediately in good condition.

In the Hayden case, the accused was proved to have bought eight grains of morphia, one and one half of which were wanting from the package. He said "he thought his sister might want it." When was this morphia given, if given at all? Probably a large dose to allay the terrible distress caused by the first shock to

the nervous system, at twelve o'clock, two hours after the arsenic; hence the sleep and dizzy head of the morning and freedom from pain during the day following.

Morphine was not detected by the chemists, but our best authorities state that neither opium nor its alkaloids can be detected once in ten cases of fatal poisoning. Wormley says, "Thus far, with few exceptions, there seems to have been an entire failure to recover the poison from the tissues in poisoning by opium and its active alkaloids."

Taylor confirms the same view. This is accounted for by its rapid absorption, and when once within the tissues it probably loses its chemical constituents. Any considerable amount *remaining in the stomach* after death may be detected, if sought for immediately.

The counsel for defense did not deny the finding of arsenic by Drs. Hill and Wood, but boldly took the ground that no symptoms of arsenical poisoning existed until about the time of or soon after the first visit of the attending physician. It suited their purpose to make the theory of arsenical poisoning an exact proposition; each symptom was made to appear in its regular order of succession, and to follow in a given number of minutes. The dose given, the time the patient would live, and each step of decadence could be determined with mathematical exactness. The plan also included the presence or absence of post-mortem changes, the diffusion of arsenic through the body after death, a well-established pathology, embracing many occult morbid processes, never before determined, all methodically arranged to fit the case under consideration, and limit the period of arsenical poisoning to the interval between the first visit of the attending physician and the death of the patient. They employed a single medical expert, Dr. Joshua B. Treadwell, of Boston, who gave the following testimony. "I quote from the government's stenographic report. 'If ten grains of white arsenic had been given, it would have been followed within twenty minutes by more or less disturbance about the stomach and bowels; in half an hour by vomiting and severe pain; within an hour and a half severe purging, paleness of the surface, slow pulse, and great prostration generally, and death probably within ten hours.' 'If morphine had been given with the arsenic the patient would have collapsed more rapidly than if it had not been given.'

The defense then gave results of autopsy, and asked "how long before death arsenic had been given, if there was only a trace found in the brain?"

Answer. "Only a few hours.—*inside of five hours.* If it was in excess of that time there must have been a large amount of arsenic in the brain; it is carried there in large quantities." "If a person lives five minutes after a dose of arsenic is put in the stomach, arsenic will be found in the brain;" "it can be found upon chemical analysis in small quantities." "If they live a few hours it is found in large quantities."

District Attorney Staples asks, "If you found only a trace, would you suppose it given within five minutes before death?"

Ans. No, sir; might have lived two or three hours. In two or three hours would get a larger trace than in five minutes.

Ques. Does the process of deposition commence slowly?

Ans. Yes; the whole process is a slow one.

Ques. Is the arsenic first found in the blood or in the tissues?

Ans. It is in the blood, but as soon as it is in the blood it is absorbed.

Ques. Does arsenic cause fatty degeneration of the liver?

Ans. When its use is prolonged over a number of days, and *only then.* It consists in a normal tissue being substituted by a fatty tissue, and is a slow death. In case the liver shows a large amount of arsenic, with only a trace in the brain, the fact would be that a large amount of this arsenic had passed out of the stomach after death. It is a recognized fact that arsenic diffuses itself after death.

I have cited a few passages from Dr. Treadwell's testimony, showing its character, believing that the statements of medical experts belong to the profession, and are proper subjects for criticism by its members.

FITCHBURG, January 28, 1880.

RECENT PROGRESS IN THE TREATMENT OF THORACIC DISEASES.

BY F. I. KNIGHT, M. D.

Asthma not a Neurosis.—Dr. Berkart¹ has done the profession a very great service in trying to rescue asthma from the list of diseases, and condemning it to the list of symptoms where it belongs.

We hope his book may mark an era in the history of thoracic dyspnea, and such a revolution in practice as when dropsy was declared a symptom and not a disease; for asthma is in our opinion not one whit more a disease than is dropsy. The author was induced some years ago to enter upon a special study of asthma on account of its intractability on several occasions. In the pursuit of that inquiry, as he says, little perspicacity was needed to discover that the prevailing obscurity on the nature and treatment of asthma, primarily and mainly, arose from the exclusive attention bestowed upon the dyspneal paroxysms, whereas their constant antecedents and sequelae, which form the life history, as it were, of the disease, were either neglected or erroneously interpreted. It is readily intelligible, he says, that a dyspnea which, apparently independent of organic lesions, suddenly rises and as suddenly subsides cannot but be the subject of much speculation. A close examination, however, of all the facts connected with asthma enabled the author to conclude that this was merely one link in a chain of morbid processes, that commenced with a more or less insidious inflammation of the pulmonary tissue, and terminated with bronchiectasis and emphysema. These views were presented to the Medical Society of London in 1873. Subsequent observation has confirmed them in the author's mind.

The Introduction and History of Asthma, as indeed the whole book, show careful and exhaustive research, due credit being given to those, as Beau and Traube, who have previously denied its existence as a substantive disease. The reader will remember that Traube considered "asthma nervosa" nothing but an acute bronchial catarrh.

The discussion of the prevalent theory of asthma (that is, that it is a nervous affection) is exceedingly in-

¹ On Asthma: Its Pathology and Treatment. By J. B. Berkart, M. D. London: J. and A. Churchill. 1878.

teresting, and should be read in full. The arguments in favor of this theory are that there are cases in which an intense and agonizing dyspnoea suddenly arises in the midst of perfect apparent health, and as suddenly relapses again into a state of ease and tranquillity. There are no physical signs of any organic disease; hence independence of the disease on structural changes is inferred. This inference tallies with the freedom of respiration, which is immediately restored after the attack. It is confirmed by the results of post-mortem examinations, which are reported to be either completely negative, or so varying in character as to preclude the idea of their being the cause of a definite disease. Upon the principle that affections which leave no traces of their existence produce their symptoms through the nervous system, asthma is supposed to be a nervous affection. To the same conclusion tend the causes, symptoms, associated phenomena, periodicity, and treatment of the dyspnoea; all these directly appealing to or acting through the nervous system. In reference to the *inference from the absence of physical signs* the author justly remarks that in the present state of pathology it is superfluous to say that there are other recognized affections besides heart disease, bronchitis, and emphysema capable of producing sudden and intense dyspnoea; but not even these latter can be excluded on the grounds assumed. A patient may daily expectorate several spittoonfuls of mucus, and yet the most practiced and careful observer may fail to detect, by means of percussion and auscultation, the least trace of disease. Again, many cases of emphysema exhibit no typical symptoms, as described in text-books. The same may be said of diseases of the heart. The fact is, says the author, that auscultation and percussion reveal only "coarse" organic lesions, and these, moreover, under special favorable conditions. This comparative short-coming detracts in no way from the importance of these methods of examination. After all they are but one, though an invaluable, aid to diagnosis. They do not, however, supersede but supplement the other results of clinical observation, and only by their combined consideration is it possible to arrive at true conceptions of the nature of a disease. Hence the seeming inadequacy of physical signs during and after an asthmatic paroxysm is insignificant in itself. A more comprehensive view of the case, one not limited to prominent symptoms, but including all its symptoms, its antecedents, and sequelæ, fully accounts for its pathology. Such a survey shows that asthmatics are "generally miserable looking-wretches, round-backed, cyanosed, veiny, and thin,"¹ or prone to obesity at an early period of life, — a sign of premature senescence. Ninety per cent. of them have, previous to their first attacks, suffered from inflammatory affections of the lungs, from which, although the acute symptoms have subsided, they have never completely recovered; and after but a short persistence of the asthma there invariably appears emphysema, — a disease, so far as its pathology is known, essentially chronic in its development. In the face of this evidence, it would be casting aside the accumulated experience of centuries to assert that with such antecedents and sequelæ the respiratory organ, constantly the seat of functional disturbance, is nevertheless in a sound condition, because auscultation and percussion show nothing to the contrary.

In reference to the *inference from the freedom of respiration between the attacks*, the author says, complete freedom of respiration is not inconsistent with such impairment of the elastic tissue of the lungs, for even in many cases of fully developed emphysema there is no dyspnoea so long as there is no bronchitis. In health and quiet respiration, only one third of the lungs is employed for the performance of the function. Subjective dyspnoea takes place only when the respiratory surface is reduced below that proportion.

With reference to the *alleged negative results of post-mortem examinations*, that with few exceptions they date from a time when pathological anatomy was yet in its infancy, and the term asthma was used still more promiscuously than it is now, and then the author makes the remarkable statement that, so far as he is able to ascertain, modern literature contains only two cases in which the asthma was not accounted for by the post-mortem appearances.

With regard to the positive results of post-mortem examinations, the author says that in the vast majority of instances pathological conditions are and have been met with. Their alleged variety, however, applies only to cases of a former date, and proves not that asthma is independent of anatomical lesions, but that the term has been indiscriminately employed. At present, when, as already mentioned, the limits of the disease are greatly restricted, the organic complications are consequently also of a more definite character, and more constant in their appearance. Even the pure and idiopathic asthma (if it is at all severe) is soon accompanied by structural changes, which, according to the prevalent doctrine, are believed to be the *consequences* and not the *causes* of the dyspnoeal seizures.

Yet the principle upon which this opinion is based is quite inconsistent with the teaching of modern pathology. No shadow of a proof can be adduced to show that in any case derangement of function causes derangement of texture. If the functional disturbance apparently precedes the organic lesion, the latter is merely at the time inaccessible to diagnosis. And, lastly, the pathology of emphysema is equally inconsistent with the prevailing opinion. Asthma can produce a loss of elasticity and a permanent distention of the lungs only by the disturbance of the respiratory pressure during the paroxysms; yet such mechanical force is ineffective unless there be a predisposition adherent in the lungs. The facts that at times emphysema spontaneously arises, as it were, and precedes the bronchitis, the cough, and the dyspnoea; at others rapidly and extensively develops when the disturbance of the respiratory pressure has been but slight and of short duration; and again at others gradually appears and to a limited extent when the same causes have been persistent and powerful, — all these forcibly show that certain nutritive changes of the pulmonary tissue are concerned in the production of that disease (Biermer et al.). The nature of these changes is as yet unknown, and for the present purpose it is immaterial whether it consist in an extension of the catarrhal inflammation from the bronchial tube, or in a primary disease of the alveolar walls (Villemin), or in thrombosis of the pulmonary vessels, followed by softening and absorption of the elastic tissue (Isaaksohn). It suffices for the present purpose to state the fact that even if asthma is pure and idiopathic it is soon complicated with emphysema, and

¹ Hyde Salter.

as the dyspnoæal seizures furnish only the mechanical element it therefore follows that under these conditions the lungs cannot be healthy, but must be the seat of pathological changes.

Hence the principle that "diseases which leave no traces of their existence produce their symptoms through the nervous system" (Hyde Salter) is, whatever its merits may be, inapplicable to asthma; for though in a few and rare instances the lungs may seem perfectly sound, still there is no evidence that they are so, whereas the symptoms and the results of post-mortem examinations tend to opposite conclusions.

In answer to the question, *Is asthma a bronchial spasm?* the author says that in the vast majority of instances the bronchial muscles are so greatly impaired in nutrition as to be incapable even of contracting. When the dyspnoea has lasted for some time, the dilatation of the air tubes becomes permanent, and indeed the most dilated bronchi Hyde Salter has ever seen were in a case of "spasmodic asthma." It is superfluous to add that under these conditions the contractility of the bronchial muscles is utterly destroyed.

The chapter on Definition, Pathogeny, and Ætiology is equally interesting. The author begins with the statement that the intense and intermittent dyspnoea, which, mainly on account of its fitful appearance and departure and its seeming independence of structural lesions, has been hitherto attributed to a derangement of innervation, is in reality due to pathological changes of the lungs. That asthma is a mere symptom can readily be proved. The recognition of this important fact has been greatly impeded by the exclusive attention paid to the clinical features of the paroxysm, and by the persistent attempts to deduce from them alone the nature of the dyspnoea.

With the exception of the comparatively rare instances in which the dyspnoea is produced by a foreign body in the air passages, asthma generally gives fair warning of its approach. Those subject to the disease have, previous to the appearance of the typical paroxysms, suffered from an acute or chronic inflammation of the respiratory organs. Of the two hundred and twenty-three cases collected by Hyde Salter, the original cause of asthma was not ascertained in forty; in one hundred and thirty-two out of the remaining one hundred and eighty-three cases the original causes were stated to be chronic catarrh, colds, and catarrhal pneumonia, complicating whooping-cough, measles, and typhoid fever.

From these statistics it appears that bronchitis and catarrhal pneumonia have preceded dyspnoæal seizures in eighty per cent. of all cases. It is needless to add that this great frequency is not a mere matter of accident, but points to a certain relation between the events. What influence bronchitis and pneumonia have upon the origin of asthma will be evident from their anatomical details. In sixty-two per cent. of those cases the inflammation occurred in the first decade of life, and was either idiopathic, or a complication of whooping-cough and measles. Now, in feeble, narrow-chested children, and in those affected with thoracic deformities especially (and these supply the greatest contingent of asthmatics), bronchitis, though commencing in the larger, has the tendency to spread to and even beyond the smaller tubes. Under these circumstances the bronchial wall is inundated with a gelatinous, synovia-like substance (Roki-

tansky) consisting of serum and white blood corpuscles. The same kind of exudation exists also in the interlobular tissue, and here diffuses itself so as to reach even the pleura. Some of the alveoli are inflamed; some are filled with aspired mucus; others are in a state of atelectasis; and again others are the seat of a vicarious emphysema (Ziemssen). There can be little doubt that if an individual—child or adult, who up to a certain time enjoyed good health—be attacked with what seems to be a bronchial affection; that if from this he apparently recovers but remains henceforward subject to asthma, this strongly argues that the respiratory organ has been permanently injured by the preceding inflammation. There yet remains a minority of instances in which asthma is apparently congenital or spontaneous. But the question is, how far, on the one hand, congenital atelectasis, and how far on the other those insidious interstitial changes of the pulmonary tissue, are responsible for it.

Hence the antecedents and sequelæ of asthma manifest themselves by their nature as *one continuous though protracted pathological process. Asthma, therefore, is only one link in a chain of quasi-independent affections, which commences with inflammatory changes of the pulmonary tissue, and terminates with emphysema or bronchiectasis.* Thus, according to this definition, "the essential or idiopathic asthma" of writers corresponds to the dyspnoea accompanying the gradual and latent progress, and their "symptomatic or catarrhal asthma" to the fully developed state of chronic bronchitis and emphysema.

The present inquiry has shown that the tendency to asthma is produced by definite organic lesions of the respiratory organs; only the imperfect means of diagnosis and the rarely fatal issue of the disease at the time when its clinical features are most interesting are the cause that the existence of those lesions has been so constantly overlooked. Still, the known pathology of the antecedents and sequelæ permits the safe inference that the stage intermediate between them also corresponds to certain textural changes.

In regard to the immediate causes of asthma the author says that, notwithstanding the textural changes of the lungs, respiration continues to be undisturbed, and this perfect freedom of one of the most important functions is mainly due to the beneficent activity of compensatory forces which here, as elsewhere, tend to the preservation of health, even under the most disadvantageous circumstances. Those compensatory forces, however, have their limits. They prove inadequate in the face of an additional obstacle, to respiration. Thus, the accession of an obstacle, however trifling in itself, is sufficient to provoke an asthmatic seizure.

The immediate causes of asthma are numerous and of various kinds, but all productive of the same result,—obstruction of the bronchi. They are exhibited in the following table:—

- I. Hyperæmia and œdema of the lungs.
 - (a.) Relaxative { Inhalation of irritating gases.
Inhalation of dust.
Thermal influence.
 - (b.) Collateral { Meteorismis.
Embolism of the pulmonary artery.
 - (c.) Reflex paralytic.
- II. Bronchitis.
- III. Stenosis of the bronchi { Foreign bodies.
Constriction.
(To be concluded.)

Reports of Societies.

WINTER MEETING OF THE COUNCILORS OF THE MASSACHUSETTS MEDICAL SOCIETY.

THE councilors of our State Society held their winter meeting at the Medical Library Hall on Wednesday, February 4th. Dr. Lynian, president of the society, called the meeting to order at eleven A. M. The first business in order was the reading of the records of the October meeting, by Secretary Goss. They were accepted without comment.

Delegates from the state society to the societies of other States were then named and accepted. — The president nominated Drs. Stedman and Edes as auditors of the treasurer's accounts; Drs. Langmaid and Wadsworth as examiners of the library; and Drs. Presbry, Hosmer, and Millet as committee on by-laws of district societies. These nominations were confirmed by vote. The report of the committee on membership, Dr. James Ayer, chairman, was presented and accepted, but it gave rise to a discussion upon the case of a Fellow whose dues amounted to sixty-one dollars, and who for five years had not responded to treasurer's notices. The committee proposed, therefore, to drop him from the roll. — Dr. Bronson, of Attleboro, expressed the opinion that if this man could pay he should be made to do so, and then be dropped, and offered this opinion as a motion. — Dr. Millet, of East Bridgewater, proposed as an amendment that the individual should first be allowed to resign, and afterwards be dropped. A Fellow who is merely dropped can afterward come into the society and vote, and in such case the society has no remedy. — Dr. Minot, of Boston, hoped the motion would not prevail, because a man who would not pay his dues, nor even reply to notices from the treasurer, of course would not resign. Such a man should be dropped, and he is provided for in the by-laws. By-Law VII. to this effect was then read. — Dr. Millet replied that such a man should be forced to resign; otherwise he will come in and vote. — Dr. Minot answered that a dropped man is not on the catalogue, and so never comes to society meetings. — Dr. Ayer coincided with this view, and thought that to allow a man to resign would establish a bad precedent and make trouble. The question being voted upon was decided in the negative; the recommendation of the committee then received an affirmative vote.

THE CODE OF ETHICS.

The code of ethics was next brought up. There were two reports upon the table: one, the majority report of four members of the committee on the code; the other, the minority report of one member, Dr. Bigelow, of Boston. — Dr. Ellis, of Boston, moved that the minority report be first taken from the table. — Dr. Williams, of Boston, alluded to the great labor and time which had been expended upon the majority report, and thought that it should first be considered. — Dr. Ellis withdrew his motion, and the majority report received precedence. — By vote the minority report was then taken from the table. — Dr. Wellington, of Cambridgeport, moved that the majority report be adopted by the council. — Dr. H. I. Bowditch hoped that as a whole it would not be adopted. He had been in practice fifty years, and in that time had never read a paper so derogatory to the profession. — Dr. Wellington supposed the council had concluded

to adopt a code of ethics. The original committee of three had unanimously presented what is now the majority code. It was then recommitment to them, and their number increased by two. Now the same code comes back signed by four out of five. The committee had read everything relating to codes, had corresponded with a vast number of societies, and used every means to perfect the majority code. Four had accepted it, and it was natural to suppose that the majority of the society would be satisfied with it. The committee, having been directed to make a code, naturally believed it must include details and meet a variety of cases. It is not enough to favor the golden rule and suppose every doctor to be a gentleman. He did not see why the code should be rejected because of its detail. The committee intended nothing derogatory, but their best to present what seemed needed. He then gave instances in which detail would be necessary. He objected to the minority report simply because of its very lack of detail. The majority code had been honestly and earnestly constructed, and was well put together. He hoped those who objected to it would keep silence and accept it. — Dr. George C. Shattuck, of Boston, said that at the last meeting of the council delay had been suggested in order to give councilors time to study the majority code. He had studied and found it excellent. It is needed to cover cases occurring at all times. In a large society were all sorts of members, and therefore many minds to meet. He favored the adoption of the majority code. — Dr. Ellis remarked that at the last meeting the council had been told that the committee intended to do nothing derogatory to the society. The question is, Have they done so? For thirty years he had supposed he was practicing among gentlemen. If the majority code be true, then he had been mistaken in thinking the profession stood upon an honorable foundation. He was not willing to believe it such as is suggested in this code, and thought the minority code covered the whole ground. — Dr. Clarke, of Worcester, said he knew the minds of his colleagues in Worcester, and could say that there was but one opinion, which was that the minority report was the one the society should adopt. He and his associates had a strong feeling that the longer report suggested practices which are not common. Thereupon he read certain sections of the report, saying he could not believe such cases as were therein implied could ever occur. He thought the minority report sufficiently long for all purposes. — Dr. Adams, of the committee, then said he believed the general feeling to be in favor of the majority report. There is a wide difference between city and country practitioners. Among the latter, especially, are young men unfamiliar with many points of courtesy. They want and need details. A young man through ignorance of good manners might easily commit a breach of decorum. Hence he requires detailed and not merely suggested advice. — Dr. Williams said that codes were not intended to present the terrors of the law, but as instruction. Sons of physicians are familiar with ethics from their youth. Other young physicians are not, and many of those present in their younger days would have been glad of such detailed advice as is given in the majority code. He did not think such instruction, for men who need it, derogatory to the profession. It is simply intended for the prevention of mistakes. — Dr. Brown gave instances of glaring unprofessional conduct which he

thought would be prevented by the majority code. — Dr. Henry J. Bigelow alluded to Dr. Williams's reference to physicians' sons and the need of ethical instructions which young physicians feel. They do need it, but when he began practice even with an example before him, he often felt at a loss as to the proper line of conduct. If he had had this minority code he would not have made mistakes, for whenever there is a rule in the majority code, in the minority code is a reference to the principle which covers it. He then related his method of drawing up the latter code. In the majority code he found selections from every code which ever existed. It is mediæval, prehistoric. It is not Dr. Cotting's code. It includes sections taken from codes written in times of rapacity between medical men; in times when doctors fought in the consultation room. It contains no appeal to high motives. They are the true and real influence. The whole thing is so diluted and repeated that it is impossible to extract a rule from it. Finding it such a mass of involved rules, he went carefully over it, and made selections in order to class them under a few heads. He also discovered new heads under which principles and practice might be combined. Having done this, he would assert that all objectionable matter had been omitted, and that everything necessary had been mentioned at least once. Fees and fifteen-minute consultations have nothing to do with morals. The important thing is the relation of patient to physician. The great point is to prevent physicians from stealing patients. He did not think the majority report provided for that. There are thousands of ways in which this is done. The majority report needs boiling down. Every important thing in the large code is in the small one. If, in the future, it be necessary to add any point it can easily be done under the proper head. He would defy any man to do this with the majority report. If we struck anything out of it, we should find it there again, because it contains so much repetition. In regard to the fact that four members of the committee stood against one, he would confess it to be unfortunate. The odds were great, and arose from his inability to attend any meeting of the committee. One member, even, had signed the majority report before he had seen the minority code. — Dr. Bronson thought the elder members of the council must either have forgotten their young days, or have gained a knowledge of ethics in some miraculous way. In their eyes the majority code is so elementary that they scout at it. They do not realize the need of it among young men. When they call it hodge-podge, and say it was made for knaves and fools, it is evident that they do not know in what spirit it was drawn up. Instead of its being mixed he found it to be in three distinct sections and constructed with great simplicity. The Bigelow code is concise and to mature minds apparently satisfactory. He then added the amusing remark, "Like its author, it is admirable so far as it goes;" which remark left upon his audience a delightful sense of ambiguity. Dr. Bronson concluded by saying he would not admit that there were fools in the society. If there were, then the censors had not done their duty. But there may be knaves, and the majority code is needed for them. He hoped it would be accepted, because it did not cover one point which would not at some time come to the surface. He challenged any member to point out a useless clause.

This Dr. Bigelow proceeded to do to the satisfac-

tion of his adherents, and closed with the incisive remark that he did not wish the public, especially the lawyers, to know that he belonged to a club in which it was found necessary to make a law to the effect that members shall not steal spoons. — Dr. Clarke then said that the details in the majority code are not necessary to a great and liberal profession. If a man has not a sense of honor and instincts of courtesy, this mass of information will not implant them. He had submitted the code to an eminent jurist, who said he was surprised that such rules were found requisite. Lawyers find no necessity of such suggestions. Something must be left to courtesy. He thought the majority code belittling, and unworthy of the society. — Dr. J. Collins Warren spoke on behalf of the young men for whom so much solicitude had been expressed. It was very kind on the part of the committee to wish to instruct them, but if the matter were left to the young men he thought they would have no code at all. They knew the society had lived peacefully for nearly one hundred years without a code. Why could not this state of things go on for another century without the aid of this useless mass of rules? — Dr. Millet said that the gentlemen who had spoken seemed to have lived on a higher plane than the commoner practitioner. He did not believe the country physicians, in particular, required the code, but he had known instances of great professional discourtesy, — instances for which these gentlemen think it unnecessary to provide. He cared nothing for the code of ethics so far as his medical neighbors were concerned. Still, there is a want of something to which all the district societies can refer, and which can be used as a guide. — Dr. Reynolds, of Boston, said he did not wish to reflect upon the purposes of those who have drawn up the codes, but he decidedly objected to both reports. He thought the will of the society had not been met. Having been secretary of the committee, he could say that there had not been one word of discussion in the committee during the fifteen months of its existence, and only once a quorum. No kind of compromise, therefore, had been formed. He had signed the majority report because, up to within twelve hours of the meeting, he had not been able to see the other. When he did see it he rather preferred it. He had no reflections to make upon the laborious efforts of the chairman, but the committee had not done what he supposed they were appointed to do. He hoped the reports would be referred to five good, honorable men, within easy reach of each other, who might thoroughly discuss and condense them. — Dr. Bronson expressed the belief that if the majority report were adopted it would silence reports which are flying over the State to the effect that certain members of the society had done things for which there is no remedy.

Dr. Cotting, chairman of the committee, then said that, though he had no right to speak, he wished to repel wholly and thoroughly the imputations cast upon the committee and their work. They had met as often as they could meet. Dr. Bigelow had been unable to attend meetings. Dr. Reynolds had had two hours' (private) discussion with him. What has the council done for the committee? They had done their best. They had gone as far back as they could go in research. They had taken every *live* thing they had found, but the code had nothing mediæval in it. He gave instances proving need of detail; said the

code had been submitted to literary, legal, and clerical gentlemen, all of whom had pronounced it as nearly perfect as a code could be. The committee had a special reason for every section. — Dr. Pineo, of Hymannis, then suggested, since the code was said to have been made for young men, and since they are now more cultured and polished than formerly, that the *unwritten* code should be the only guide.

After various other desultory remarks, the question as to the adoption of the majority code was called, and voters carefully counted. Dr. Reynolds proposed that the vote should be informal. To this, objection was made, and the result was nineteen yeas and fifty-four nays, thus defeating the majority code. On motion of Dr. Clarke the minority code, prepared by Dr. Bigelow, was then adopted by vote of a majority of the council.

THE ADMISSION OF WOMEN.

A communication from the censors of the Suffolk District Society and the society at large was next taken from the table. It asked instruction in regard to the admission of women for examination. The censors doubted the legality of the position in which they had been placed by the October vote. — The reading of their communication was voted down. — Dr. Hodges then moved that the October action of the councilors in regard to females be referred to the general society for its consideration at the next annual meeting. — President Lyman said that in reading the paper in question he found there was a legal point of importance yet to be settled. He thought it should go to the general society for their concurrence. — Dr. Millet doubted whether a decision could be reached without the concurrence of the legislature. — Dr. Bronson understood that at their last meeting the council decided that the pronoun *he* meant male or female. He believed the protest of the censors to be an honest creation. He had heard it called "a trick," but did not believe it to be so, and was therefore willing to accept the opinion of the board of censors, and thought their reasoning sound. — Dr. Lyman said the censors had applied to him for information in the premises. He replied that he had no right to authorize them to proceed in the face of the sharp legal point involved. — Dr. Reynolds regretted the action of the October meeting. He did not consider that a fair and honest chance had then been given the question. It attacks the very existence of the society. Councilors should not wish to bring it before the general meeting without previous and full discussion. — Dr. Hodges then withdrew his motion. — Dr. Pineo moved that the council reconsider the vote of the councilors at the October meeting, whereby censors were instructed to admit women for examination. — Dr. Bronson said he did not object to Dr. Pineo's motion in the abstract, that is, as touching the legality of the decision; but on any other ground he opposed reconsideration, for it is boys' play to reconsider when a large vote has been taken. — The motion of Dr. Pineo was then voted upon and decided in the affirmative. This tabled the woman question. The meeting then adjourned.

— Voltolini claims that the only proper position of a patient during an operation for the extraction of a foreign body from the ear is upon the back on a table, the head being allowed to hang over the end.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

F. C. SHATTUCK, M. D., SECRETARY.

MYELITIS, ACUTE AND SUB-ACUTE, WITH A REPORT OF EIGHT CASES.

DECEMBER 15, 1879. DR. S. G. WEBBER, read the following paper on Myelitis: —

It is not always easy to decide whether a case of myelitis should be called acute or chronic. The integrity of the whole cord is so essential to its proper function that if only a small portion is affected there are irregular and defective actions in all that part below, and perhaps in parts above. If an acute affection of one segment is recovered from with permanent injury of the diseased portion, the resulting symptoms are permanent, and there is chronic derangement of function. Inflammation may begin in an acute form in the lumbar enlargement, and then advance upwards slowly, yet pathologically, with the same characters in each segment of the cord; as no vital parts are affected, life is prolonged, and the cases seem to be chronic in time, while being acute pathologically. In fatal cases, then, the chronicity or acuteness depends upon whether vital centres are attacked early or late in the disease.

CASE 1. The first case is one in which the disease ran a rapid course, with febrile action, terminating in death within two weeks from its origin.

E. F., aged thirty-four, farmer, entered the Boston City Hospital November 8, 1879. He had used liquor for fifteen years, in small quantities, but said never to excess. There was no specific history. November 3d, he drove twenty-five miles in the rain and snow, getting his legs wet; he felt chilly on the road. During the day, November 5th, he worked in a barn cellar; he worked hard and was heated. In the evening he worked in a cold milk-house, on his hands and knees. He felt quite chilly while at work, and more so on leaving off. In the night he walked to the water-closet, and there found that he could not pass his water. On the morning of the 6th he rose, dressed himself, and sat by the stove. In half an hour he found that his legs were feeling stiff and weak; he required help to get to his bed. The feet were numb, pricking as if pins were stuck into them. There was no pain except from a full bladder, which was relieved by catheterization; no sense of constriction. The numbness began at about the crest of the ilium; the legs when tested proved to be less sensitive than normal. There was no reflex action on tickling the soles of the feet; tendon reflex was absent. There was entire loss of voluntary motion in both legs. There was no spasmodic action. The temperature was high, running up to 104° F. immediately after his admission, but in three or four days it descended to 101°, and subsequently to the normal, when he died. The pulse followed nearly the same course. The anesthesia crept upwards, breathing became abdominal, and on November 18th, thirteen days after the origin of the disease, he died.

Autopsy by Dr. Cutler. Cord: From a short distance below brachial enlargement, the cord had an irregular, lobulated surface. On section just below the cervical enlargement, there was a considerable amount of hemorrhage into the gray substance. The difference of color between the healthy gray substance and that where the hemorrhage occurred was obscured by the hemorrhage, but it seemed to be decidedly less gray. Below, the lateral columns were quite gray,

softened, and in them were some small hemorrhages. The boundary between the gray and white substance was difficult to make out. The cord below was extensively diseased, the most marked changes, however, being in the few inches below the cervical enlargement. Other organs healthy.

CASE II. The next case is one running a protracted course, which began with less decided symptoms and progressed much more slowly, continuing about fifteen months. Though of such long duration, there was no other element by which it would merit the title chronic. The course, excepting a slight remission under treatment, was steadily progressive; apparently the disease extended slowly through the length of the cord, retaining the same character throughout. This case well illustrates the dangers in myelitis from bed-sore, cystitis, etc.

H. S., single woman, aged forty-four, was seen first in March, 1875. She had always worked hard, for the last twenty years as a laundress. She was much on her feet, and they were often wet. The spring previous she had worked more than usual. One day in May she worked until twelve o'clock at night, washed lace curtains, and rinsed them out in very cold water, the hands being very cold. The next morning the left thumb was numb, "sleepy," around the end on the palmar side; she felt feeble, too, and nervous; going up-stairs, she was tired through the thighs. In about a week both hands were numb; three or four months later the legs were affected. She could walk, however, until October, when she noticed that she staggered. There was some fibrillary tremor in legs. In December, the legs drew up and a sharp pain darted through them. There was a sense of constriction about the abdomen, with distress in breathing. The bowels were confined; she had had retention of urine. Motion of arms caused pain through the ribs, not in the back, but motion of the legs caused pain in the back; straightening of the legs caused a dragging sensation in the back; turning in the bed and twisting of the body were painful.

During the visit, the legs were drawn up much; there was hyperesthesia in the hands, but no spasmodic action. Sensation was much impaired in feet; reflex action was exaggerated; there was tenderness over the upper dorsal vertebrae. Most of the muscles of the leg responded to the faradic current. The vasti interni were the only muscles which did not contract.

Under treatment, using galvanization, iodide of potassium, and ergot, she gained somewhat, the spasmodic action and pain or discomfort being much diminished, and she slept much better; but the improvement was only temporary. Two bed-sores were formed, on the right hip and right side of back; there was first incontinence of urine, then inability to pass it. Cystitis appeared, and it became necessary to wash out the bladder daily. The spasmodic action returned for a short time, then contraction of the muscles set in, the adductors being especially contracted, so that it was difficult to separate the legs to use a catheter.

July 28th, there was entire loss of power in arms and hands; the hands were oedematous. The legs were continually and strongly adducted; a very slight touch caused spasm; when the catheter was passed there was spasm of the adductors and flexors of the thighs, and if the catheter touched the walls of the bladder there was the same spasm. There had been involuntary movements of the bowels. The skin had

been several times jaundiced; there was nausea; heat in back; the legs varied, sometimes being hot, sometimes cold. The mind was somewhat affected; memory failed. She died August 2d.

Autopsy two hours after death. There was considerable fat over the whole body. The muscles of the right thigh had a natural color. Under the pleura were small hemorrhages and spots in the lungs, which were more solid and darker colored than the rest; the bronchi contained much mucus. All the other thoracic and abdominal organs were healthy.

Brain: Membranes clear; convulsions rather shrunken; sulci deepened. On the left the anterior parietal convolution was not regular, and near the median fissure was a depressed spot; on the right side, anteriorly, was a depressed spot of less extent in the first frontal convolution.

Cord: Of good consistency; nowhere did it bulge up from the cut surface, not even in the dorsal region, where it was softer than elsewhere. In the upper dorsal region the section was more yellow than elsewhere. The membranes and the vertebrae were healthy. Microscopic examination: In a fresh condition, the upper dorsal region showed a very large number of granular corpuscles, and these were abundant in the walls of the vessels in the adventitia; there were also many oil globules.

CASE III. A young man, Mr. B., was seen in 1873 in consultation with Dr. Davis and Dr. Bowditch. He had been living in the West in a malarial country, but had not had fever and ague. He was employed out-of-doors, exposed to the weather, and was in the habit of crossing the river on the ice during the winter, often going all day with wet feet. He had no heavy work to strain his back. His first symptom was a slight sensation of numbness in his feet, an absence of feeling, and pricking as if they had been asleep. This sensation was in his feet alone at first, but gradually crept up the legs, so as in two months to interfere with walking. He was not very weak, but his feet were clumsy, and he could not lift them from the ground enough to prevent tripping. The numbness reached in patches as high as the hips. There was no pain. Under treatment he improved slowly, and in about six months he considered himself well. He remained well for nearly a year; then, while traveling and living a rather irregular life with regard to eating and sleeping, the numbness reappeared in the right foot and arm, with loss of power, but less pricking, and in two or three weeks he had to give up walking. He was not exposed to cold and wet before the second attack. Within a week of the commencement of these symptoms in the right side the left side was affected. There was more numbness than loss of motion on the left; on the right both sensation and motion were equally affected. In some positions the right leg trembled; there was twitching on the right side, and the right leg was inclined to draw up spasmodically. Just before this second attack he took strychnia, on account of a remnant of old trouble in his left hand.

When seen, about six weeks after the beginning of the second attack, he could hardly move the right leg and foot, the right arm and hand to a limited extent, the left leg and arm much better. The muscles of the right fore-arm required a stronger faradic current than those on the left to excite contraction. All the muscles responded to the current, and there was no wasting. Sensation was much diminished in both legs,—

most in left. On the right two points could be felt as such, when sharp, only at three inches distance; when blunt, only one point felt. On the left, when blunt, only one or none was felt. He had had a sense of a girdle around the abdomen on a level with the crest of the ilium.

Various remedies were used in succession: first ergot, and later iodide of potassium and counter-irritation to the back in various ways. The iodide was given in large doses, lest there might possibly be a specific taint. The disease seemed to be checked for a short time; perhaps there was a slight gain, but later he became worse; some of the cerebral nerves were affected; there were ptosis on the right, partial paralysis of the facial muscles on that side, and tinnitus. The faradic reaction of the muscles was good in both legs in August. A letter was received from him in March, 1874. Subsequently he died, but the record of the date has not been kept. There was no autopsy.

In this case there was some suspicion that syphilis might have acted as an agent in producing the disease, but the evidence on that point was not clear. The case is chiefly interesting from the almost complete recovery and the appearance of the symptoms again after a less amount of exposure and overwork. The fact that strychnia was given immediately before the relapse is a circumstance deserving of special notice. I have seen bad effects following the use of strychnia in other cases of disease of the spinal cord; indeed, there are very few cases of organic nervous disease where I should feel justified in giving it.

(To be concluded.)

Recent Literature.

Elements of Modern Chemistry. By ADOLPHE WURTZ, Member of the Institute, etc. Translated and edited from the Fourth French Edition, by W. H. GREENE, M. D., etc. With one hundred and thirty-two Illustrations. Philadelphia: J. B. Lippincott & Co. 1879.

Of the numerous text-books on General Chemistry, but very few, unfortunately, are well adapted to the needs of the student. A new book on this subject, therefore, if a good one, is not out of place. This book by Wurtz is to be commended on many accounts. A relatively large part of the book is devoted to the non-metallic elements, as is proper. Theoretical chemistry (a part of the subject generally too much neglected in text-books) has received its proper share of attention. The laws of chemical combination, Gay-Lussac's laws, the law of specific heats, etc., and their relations to the atomic theory; chemical nomenclature and notation; the theory of atomicity; the different classes of chemical compounds, and, in connection therewith, the laws of Berthollet, are all treated of at some length.

Considerable space is devoted to organic chemistry. From the vast number of organic compounds a very careful selection has been made of the more important. There are also short but valuable chapters on the constitution of the carbon compounds, elementary analysis, and the various classes of organic compounds. The symbols are generally written so as to indicate, as far as is known, the constitution of the various compounds. The book is well illustrated, and the illustrations cannot fail to be of value to the student.

In these respects, as well as in others, the book is

superior to nearly all other text-books in elementary chemistry, and we can recommend it. The translator and publishers have done their part of the work well.

Photographic Illustrations of Skin Diseases. By GEORGE H. FOX, A. M., M. D. Part V. and VI. Containing plates of eczema infantile, papulosum, ichorosum and pustulosum, squamosum; and eczema barbae, manuum, e. venis varicosis and ulcus varicosum; psoriasis annulata. New York: E. B. Treat.

The photographs in these parts, as will be seen, make up a nearly complete gallery of the various stages and clinical varieties of eczema, and the accompanying text forms a small practical treatise on the affection. The latter is excellent, and we wish that we could say the same of the illustrations; but they are a disappointment, measured by the high standard of expectation warranted by the first of the series. The plates in Part V. are with one exception poor and of little service to the student, the scale of the pictures being so small as to show little more than the configuration and extent of the disease. In Part VI. they are better, but one only can be considered perfectly satisfactory, — that of eczema manuum.

The Structure and other Characteristics of Colored Blood-Corpuscles. By LOUIS ELSBERG. Printed from the Annals of the New York Academy of Sciences. New York: G. P. Putnam's Sons. 1879.

We are glad that the author of this paper has seen fit to have it reprinted. We hope it may be widely read by both physicians and students. The original investigations of the author are very good; and as a record of the very extensive literature of the subject the work is invaluable. The method of examination consists in mixing a drop of blood with a drop of a forty per cent. or fifty per cent. saturated solution of bichromate of potash, taking measures to prevent evaporation, and examining it with a high power for a considerable time. Some very curious changes are observed, for an account of which we refer the reader to the work. Then follows a concise statement of the views of others on various points, and finally we have the author's conclusions. He does not regard the colored blood corpuscle as a cell, properly speaking, but simply as "an unattached portion of the living matter (bioplasm) of the body." It seems to us that this is hardly in accordance with the similarity of structure of the corpuscles. Dr. Elsberg admits the existence of a net-work extending throughout the corpuscle. He does not believe in a "separate investing membrane," but thinks that the outermost layer, though essentially the same as the inner substance, may "be differentiated from the latter, especially at the periphery of the disk."

"In size, human colored blood corpuscles vary so much that claims to be able to distinguish them by their size from certain other mammalian colored corpuscles are inadmissible."

T. D.

—The *North American Review* for January and February contains among other valuable and timely articles a particularly good summing up of the woman question, by Mr. Parkman, and a striking contribution from Cardinal Manning, on the Catholic Church and Modern Society.

Medical and Surgical Journal.

THURSDAY, FEBRUARY 12, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, OSGOOD AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, OSGOOD AND COMPANY, BOSTON, MASS.

ETHICS AND WOMEN.

THE meeting of the councilors of the Massachusetts Medical Society, held last week, is worthy of notice as being an occasion of the presentation of two subjects of general interest to the profession. The first of these was the selection of a code of ethics, the preparation of which has for the last two or three years been in the hands of a committee carefully selected from leading members of the society. The greatest pains had been taken in its preparation, for which the society is chiefly indebted to the indefatigable and public-spirited labors of Dr. Cotting, to whom thanks are due for the very elaborate and carefully prepared document presented. During the preparation of this report, a feeling of opposition had arisen against so detailed a statement of rules for professional guidance; many indeed preferred to leave the society, as it had been for a century, without a code, and this feeling had found expression in a minority report, which was prepared by the skillful hand of Dr. Bigelow, and embraced a very condensed set of rules for the guidance of the novice in such cases when reasonable doubts might arise as to what should be the most appropriate line of conduct. After a very spirited debate, Dr. Bigelow's code was finally adopted, and we must take this opportunity to congratulate the society, if it must have a code, on the possession of a document of such a high order of literary merit, and, above all, one which shows how briefly such matters can be disposed of.

It may interest those who begin to believe that professional Boston bids fair to be conquered by the female practitioners that the council reconsidered its action by which it voted to admit women to the society, and that the question stands at the present moment precisely as it did before any action was taken. The grounds for reconsideration rested, to be sure, upon a legal point raised by one of the boards of censors, it being thought questionable whether the council could make such a law without concurrent action of the society. The matter will be brought up again at the annual meeting. In the mean time we shall hope for a change of sentiment, of which we have already seen some slight indications, or, at least, for a much more thorough debate than has yet been had upon one of the most important steps the society has ever contemplated.

— The existence of a pair of twins, eight months of age, in good health, and united from the breast bone to the lower portion of the abdomen, is reported from Bombay.

ANNUAL REPORT OF THE MARINE HOSPITAL SERVICE.

THE supervising surgeon-general of the marine hospital service has presented to the treasury department his annual report for the fiscal year ending June 30, 1879. No report was published for the year 1878, and this consequently covers the two years 1878 and 1879. It contains full and valuable tables of statistics, financial and economic, medical and surgical, and an appendix, with some interesting papers and reports by officers in the service.

During the year 20,922 seamen were furnished relief by the marine hospital service. Of this number, 11,499 were treated as hospital patients, and 9243 as dispensary patients; 331,269 days' relief were furnished, and 14,265 prescriptions were supplied to outpatients. The number of patients treated shows an increase over the year 1878 of 2699, and of 4114 over any year previous to 1878. The cost per capita was \$17.93, which shows a reduction in the cost per capita from the year 1878 of \$2.11, and gives a continuous reduction in the cost per capita since the reorganization of the service in 1870, when the cost was \$38.41. The expenditure covers all items of expenses on account of the service. The expenditures from the funds of the service for repairs were for the year 1878 \$8140.01; for the year 1879, \$5051.70.

Surgeon-General Hamilton again recommends the enactment of a law for the compulsory physical examination of seamen before shipment, as tending to the relief of the marine hospital service, and especially to the greater efficiency of the mercantile marine. In support of such a law, he advises that a severe penalty be visited upon all persons convicted of paying or receiving "blood money,"¹ which would relieve sailors of an onerous tax, and take away the incentive to the opposition now shown by the takers of "blood money." Some permanent provision is suggested for seamen worn out in service or disabled by casualty. At present they must either be retained in hospital, or discharged to become inmates of an almshouse. New pavilion hospitals are needed at Baltimore and New Orleans, and cottage hospitals at various points. The decreased per capita cost of the care and treatment of the patients of the service is thought to be owing in great measure to the system of dispensary relief inaugurated by the late Surgeon-General Woodworth, and to the establishment of the purveying depot for furnishing medical supplies in place of the old contract system.

The appendix contains several papers prepared for the annual report of 1878. The first of these is a sketch of the service and a consolidated sick report for the twenty years ended June 30, 1878, at the port of Boston, by then Surgeon J. B. Hamilton. It is an interesting and valuable contribution. There follow several reports on local epidemics of yellow fever at different points in the summer of 1878. The last paper gives notes from the cruise of the U. S. revenue steamer *Rush* in Alaskan waters, extracted

¹ Money extorted from seamen by sailors' boarding-house keepers, and paid to disreputable ship-masters and owners for the privilege of filling their crew-lists.

from the report of Assistant Surgeon Robert White. This expedition sailed from San Francisco in May, 1879, and Surgeon White was detailed as medical officer. Those of our readers into whose hands these notes may come will find them of much interest.

The report in general indicates a very creditable state of efficiency of the marine hospital service, which indeed has been constantly improving since its reorganization in 1870.

MEDICAL NOTES.

— At the present time 165 nurses are registered at the Nurse Bureau in the Medical Library Association building. During the first month of its existence the bureau supplied nurses in the ratio of one and a half per diem.

— Dr. William Budd, of London, the distinguished physician and writer, is dead.

— From the fifth annual report of the Salem Hospital we learn that the number of in-patients admitted during the year was 138, a great increase over that of any preceding year. Thirteen of these were children. The number of out-patients treated in the several departments was 1597. There have been four amputations and two re-amputations of the leg, and three of the arm, in which recovery ensued. Five patients died on the operating table from shock after undergoing amputations for injuries caused by railroad accidents. The results of other grave operations have on the whole been satisfactory. Ether has been administered in the hospital to 225 patients in all. The average number of days spent in the hospital by paying patients was 20+, and by free patients 22+. The cost of each patient per week was \$12.20. The average number of patients in the wards during the year was eight. Board was furnished 433 weeks, of which 346 were free. The hospital staff is composed as follows: Consulting physician, George A. Perkins, M. D. Attending physicians, David Choate, M. D., William Neilson, M. D., A. H. Johnson, M. D., J. P. Fessenden, M. D. Attending surgeons, William Mack, M. D., Arthur Kemble, M. D., Octavius B. Shreve, M. D., Charles A. Carlton, M. D. Ophthalmic surgeon and superintendent, David Coggin, M. D. Physician to out-patients, Thomas Kittredge, M. D. Surgeon to out-patients, T. L. Perkins, M. D. Dental surgeon, Jesse Robbins, D. M. D.

— With regard to Dr. Edes's paper on *The Relation of Drug Manufacturers to the Progress of Therapeutics*, published in the *JOURNAL*, January 15th, the *American Journal of Pharmacy* says: "The paper seems to be aimed on the one hand against the introduction of new remedies without careful chemical and physiological study, and on the other hand against the multiplication of compound medicines, frequently containing ingredients which no intelligent physician would prescribe together, or which may suit a particular case without being adapted to general application. Dr. Edes says: 'When the pharmacist informs us of active principles, or gives us preparations honestly representing a drug, he does good service, but

when he tells us why they act or when they should be used he is going beyond his province.' This is quite correct; but we wish to remind Dr. Edes that the aim and the practice of the various pharmaceutical colleges and associations is, in part, exactly that which he points out in the first part of the sentence quoted, while the condition depicted in the latter half has been brought about, not by the hoodwinking of the pharmaceutical profession, but through the easy-going credulity of the medical profession and press. Medical journals frequently extol preparations of the composition and mode of manufacture of which neither the writers of such articles nor the editors of the journals can have the remotest idea. The dispensing pharmacist is compelled to procure what the physician orders, even though, as Dr. Bolles stated before the society, he may have three or four good manufactures of extract of malt on his shelves, and be obliged to get a fifth kind, 'because it is put up in such pretty bottles.' The physician creates the demand, and in very many cases the pharmacist cannot supply it, but has to fall back upon the manufacturers. Of course it is to the latter's interest — and this is perfectly legitimate — to respond to the demand, and, if possible, to increase it. We do not blame them, as long as they can find credulous doctors to prescribe their inventions, to get up new ones whenever a bright idea, with the probability of money in it, dawns upon them; but we do not regard this as legitimate pharmacy, even though such preparations be indorsed or prescribed by professors in medical colleges. Dr. Bolles was correct in stating that physicians were more to be censured in this matter than the manufacturers or their agents, — and most decidedly more than the pharmacist, who has to gratify such whims, not unfrequently to his loss. Let the physician confine himself as much as possible to pharmacopœial preparations, and let him, as Dr. Bolles suggested, 'hold the pharmacists personally responsible for the quality of their medicines, not directing them to get this or that manufacturer's ordinary preparations, nor allowing them to shield themselves behind the names of any wholesale makers, however famous.' Not until then will the evil of which Dr. Edes complains be eradicated."

— The *Chicago Medical Journal and Examiner* gives the following interesting data of the origin of plants: "Cabbage grew wild in Siberia; buckwheat originated in Siberia; celery originated in Germany; the potato is a native of Peru; the onion originated in Egypt; tobacco is a native of South America; millet was first discovered in India; the nettle is a native of Europe; the citron is a native of Asia; oats originated in North Africa; rye came originally from Siberia; parsley was first discovered in Sardinia; the parsnip is a native of Arabia; the sun-flower was brought from Peru; spinach was first cultivated in Arabia; the pear and apple are from Europe; the horse-chestnut is a native of Thibet; the quince came from the Island of Crete; the radish is a native of China and Japan; the pear is supposed to be of Egyptian origin; the horse-radish came from the south of Europe."

—The outbreak of small-pox in the District of Columbia is interesting from the difficulty of assigning a cause through contagion to the initial case, and, moreover, to several of the succeeding cases. November 28, 1879, occurred the first case, of a colored man in the last stages of consumption, and at that date a six weeks' resident of the Providence Hospital. The case was properly isolated at once in the Small-Pox Hospital, with due means taken to prevent the spread of the disease, and death took place December 6th, the disease being of the confluent type. December 18, 1879, a second case was in the jail,—in a colored boy, eight months a prisoner. Again the authorities were unable to trace the source of contagion, the jail being an entirely new structure. Both the hospital and jail are in what is termed the southeastern section of the city, and since that date to January 22, 1880, fifty-seven cases have occurred, with ten deaths; the health report for the week January 10th to 17th gave twenty new cases, of which two were confluent. These cases are no longer confined to the colored race, as thirteen of the last were among the whites. With the exception of a very few isolated cases, the most of these have been confined to the southeastern section of the city. The record from January 18th to 22d shows a decided decrease in the fact that only seven new cases have developed.

As a consequence, vaccination and revaccination are being pushed vigorously, and the assistants to the health office performing that duty have their hands full constantly. The virus used is that of the New England Company, and its success is a matter of congratulation.

—The *Pacific Medical and Surgical Journal* says: "The new regulations of the United States Marine Hospital Service require that the metric system shall be used exclusively for all official medical, and pharmaceutical purposes, and that the Centigrade scale *only* shall be used for recording thermometrical observations. Under this rule the thermometrical observations will lose much of their value, as they will not accord in form with observations made outside of the service. The great value of meteorological observations is in comparison. The mass of our present records stands in the scale of Fahrenheit, and those of the Centigrade will be useless for comparison until one shall be converted into the other. Whether scientists will be disposed to perform the arithmetical drudgery of such conversion is doubtful. Had all nations begun with the Centigrade the result would have been grand. But Fahrenheit and Réaumur still maintain their ground in countries which gave them birth, and a whole century has not enabled the Centigrade, though confessedly preferable in itself, to thrust them away. It is somewhat inconsistent to permit the inch scale to be used in barometrical records. Not a word is said of it in the new rules. Perhaps it was an oversight not to require the metric system to be applied to the barometer also. We are more and more confirmed in the opinion expressed by us some time ago, that the hasty endeavor to push this system into medicine and science will give rise to much error and confusion.

The movement is revolutionary, and will not be accomplished at a blow. Its rapid advance in some quarters depends more on fashion than reason. We observe that a state medical society resolved on its adoption because it 'could not afford to lag behind the age.' What kind of an argument was that?"

For the sake of uniformity in medical literature it is advisable that the scale which is in most general use — the Centigrade of Celsius — be adopted universally. But, as our contemporary observes, so long as the meteorological and other records of the United States government are kept in the Fahrenheit scale, practical convenience may be of more importance than theoretical simplicity. In many American and British scientific books, however, the Centigrade scale is used. The general adoption of new methods is difficult unless old ones are authoritatively discarded. This involves the overcoming of prejudice and habit, the great drawbacks in the way of the metric system as applied to medical prescribing, but the proverbial ardor of reformers will, we hope, eventually enable "the tail to wag the dog." It may not be amiss again to mention the mode of computing the Centigrade scale in Fahrenheit degrees. The principle of the Celsius thermometer is to divide the space between the freezing point, zero (32° F.), and the boiling point (212° F.) into one hundred degrees. In Réaumur's thermometer, which is used in Russia, Sweden, and parts of Germany, the same space is divided into eighty degrees only. Therefore 180° F. are equal to 100° C. Each Centigrade degree is equal to 1.8° F. One degree F. represents $\frac{5}{9}^{\circ}$ C., or $\frac{4}{9}^{\circ}$ R. To convert Centigrade into Fahrenheit, multiply by 9, divide by 5, and add 32 ; Fahrenheit into Centigrade, deduct 32 , multiply by 5, and divide by 9. These computations, however, are inconvenient and confusing, and it is of practical service, clinically, to remember that the normal point, 98.6° F., corresponds with 37° C., and that 104° F. and 40° C. (32° R.) are also equivalents.

—In Great Britain it is commonly supposed that Dr. A. P. Stewart, of London, was the original discoverer and demonstrator of the difference between typhus and typhoid fevers. The fact is that, although Stewart was prosecuting his studies on this subject simultaneously with Shattuck of Boston and Gerhard and Pennock of Philadelphia, the two last named gentlemen published their views in 1837, in the *American Journal of the Medical Sciences*, while Stewart first presented his conclusions in a paper read before a medical society in 1840.

—Of the use of sponging with cool water in measles, Dr. Cobleigh, in the *Atlanta Medical and Surgical Journal*, says: "If physicians who are afraid of cold in measles will only try it once they will lose all fear of the method; will be happily disappointed at the prompt recovery of their patients; will find their sufferings not only mitigated, but actually shortened as well, though I do not claim abortive powers for the antipyretic plan of therapeutics; and will meet fewer troublesome complications and almost no pathological after-conditions." From experience we can endorse this excellent advice.

PROVIDENCE.

—A series of lectures has recently been inaugurated in this city upon hygienic and sanitary topics, for the benefit of women of the poorer classes. A small admission fee is charged to those whose circumstances warrant it, but tickets are distributed gratuitously to those who cannot pay. Last Thursday, Dr. Mary Safford Blake, of Boston, addressed a good-sized audience upon Sunlight, Ventilation, and Drainage. The next lecture will be delivered by Dr. Anita E. Tyng, of this city, a member of the Rhode Island Medical Society, upon the general outlines of anatomy and physiology. The only obstacle in the way of the accomplishment of all the good anticipated from this course of lectures is the difficulty in securing the attendance of that class of persons who will be most benefited by them. The same indifference in regard to such matters which renders it important that they should be instructed makes them unwilling to avail themselves of the means of instruction thus placed within their reach.

—Dr. E. M. Snow, the efficient superintendent of Health of this city, has recently been appointed supervisor of the census for the State of Rhode Island. This appointment gives universal satisfaction throughout the State, since it is made solely upon the merits of the appointee, and not from any political considerations. It may be confidently predicted that in such hands the work will be done with that thoroughness and accuracy which invariably characterize Dr. Snow's labors.

NEW YORK.

—The New York Neurological Society has had printed and very largely circulated its "answer" to the report of the state senate committee on public health relative to lunatic asylums, together with an appendix containing a large number of letters and affidavits from various individuals, and extracts from medical journals in reference to the subject.

—State Senator W. W. Astor has introduced a new bill regulating the sale of poisons, among the provisions of which are that druggists shall be required to record every such sale, and that the bottle, box, or vessel containing the poisonous substance must possess some distinctive peculiarity by which it can be distinguished during the day by its appearance and at night by its touch.

—Measles still continue to be epidemic. The anticipation that there would be a smaller number of cases in January than in December, which was founded on the temporary abatement of the disease in the early part of the month, has not been realized, as it soon increased again, so that the number of reported cases reached the large figure of 337 in the week ending January 24th. Instead of there being fewer cases, therefore, in January, there were a larger number, more than eleven hundred being reported, against 974 in December. During the week ending January 31st, however, there were 110 fewer cases reported than in the week preceding (when the maximum for the month was reached), and the number of deaths was also much smaller. From the 1st of January to the 1st of June, 1879, the deaths in

the city resulting from measles were 38, while the deaths from the disease in the first four weeks of January, 1880, alone amounted to 84. The largest number of deaths from measles ever reported in a single year was 526, which occurred in 1869, but the largest number of cases in any one year was in that just completed, namely, 2424. Dr. E. H. Jones, the assistant sanitary superintendent, states that one cause why the number of cases now appears so large is that physicians are much more careful in reporting cases than formerly. An epidemic of measles is not to be wondered at, as it is some time since it has been generally prevalent, and there are plenty of young children in the city who have never had it to furnish material for the disease. As a rule, it is not especially dreaded by parents, and instead of taking precautions against its spread it is a very common thing, if one child in a household is attacked, to put all the other children in the same room, as it is thought to be useless to attempt to escape the inevitable, and the sooner the siege is gone through with the better. The health authorities are in all cases ready to destroy the germs of the contagion by fumigation, etc., but families frequently refuse to allow the sick-rooms to be disinfected.

PHILADELPHIA.

—Dr. Charles J. Stillé, provost of the University of Pennsylvania, and "John Welsh centennial professor of history and English literature," has resigned these positions, the resignation to take place at the close of the present college year, which occurs during the summer. This announcement is very much regretted by the friends of the institution, and strong efforts are making to induce him to alter his determination.

—Prof. William Goodell had eight ovariotomy operations last year, with only one death.

—At the Pennsylvania Hospital, Professor Da Costa recently presented to the class a case of exophthalmic goitre in a well-nourished young man, in whom it was associated with cardiac hypertrophy. Rest in bed, the administration of veratrum viride (fluid extract, one drop every three hours), and the local application of an ice-bag frequently during the day caused an immediate amelioration of the dyspnoea and speedy reduction in the size of the gland. The diet also was reduced to milk and eggs, and all stimulants were excluded.

Digestion.

DR. BUMSTEAD'S NEW DEPARTURE ON THE CHANCROID.

BY F. B. GREENOUGH, M. D.

It is to be regretted that at the present time, when the great majority of eminent syphilographers have, after years of argument, discussion, or we might almost say fighting, settled down to the acceptance of certain clean-cut and well-defined ideas on the subject, a new theory should be advanced (unless it is

sustained by evidence of the most positive nature), with all the prestige and weight which the well-won reputation of our lamented colleague Dr. Bumstead's name gives to it, which, if accepted, shows that we have been all wrong from the start.

Strictly speaking, however, the theory referred to can hardly be called new, as it was first promulgated in a paper read by Dr. Bumstead in 1876 before the section on Dermatology and Syphilology, during the session of the International Medical Congress at Philadelphia. At that time the conclusions which Dr. Bumstead drew were not indorsed by the section, or rather, to be strictly accurate, a substitution was made for the most important one of them, which practically nullified the main point at issue, and as far as I know the subject has not been taken up by subsequent observers. Now that he has incorporated it, though greatly modified, in the new edition of his most valuable work on venereal diseases, which from its great excellence is so generally used as a text-book for students and for the purpose of reference by the general practitioner, it does seem that it should not be allowed to pass without a protest, ungracious as it may appear so soon after the loss the profession has sustained by his death.

The chancreoid, soft chancre, or local venereal ulcer as at present understood is a pathological entity possessing certain marked and constant characteristics which distinguish it from the indurated chancre, and all other forms of ulceration or lesions of continuity of the cutis or mucous membranes.

First and foremost of these characteristics is the fact that it is always the result of the absorption or inoculation of the secretion of a chancreoid, and it has the property of being able to reproduce a chancreoid in its turn, by means of the specific virus contained in its secretion. Then its course, appearance, and duration are different from other forms of ulceration, and remarkably uniform. Starting as a pustule at the point of absorption, it soon increases to a fair-sized ulcer, the edges and base of which are characteristic, namely, the former sharply cut, as if done with a punch, and the latter covered with a yellowish-gray pulsatous deposit which cannot be wiped off, and which is entirely different from a slough or any other appearance seen in ulcerations. It might perhaps be compared to what we see on a granulating surface at the very commencement of an attack of hospital gangrene. Unless hastened by proper treatment the duration of a chancreoid is from four to six weeks or more, and on its duration the general health or recuperative power of the patient does not seem to have any influence, excepting of course those cases of very debilitated individuals where the phagedenic action sets in.

Another point of individuality is the fact that in quite a large proportion of cases of chancreoid the nearest lymphatic gland is affected, either by simple inflammatory action which we call, *faute de mieux*, sympathetic, — and this, by the way, may be out of all proportion to the amount of inflammation or irritation of the sore itself, — or by the actual passage of the virus of the sore along the lymphatic vessels until arrested in a gland, where it sets up inflammation of necessity resulting in suppuration, the pus so formed possessing the properties of the parent chancreoid, namely, the power of reproducing other chancreoids.

Even from this very imperfect sketch it must be evident that in the chancreoid we have a typical individuality which differs in many well-marked respects from the indurated chancre or primary syphilitic lesion, or other forms of ulceration.

The conclusions which Dr. Bumstead drew from the paper read by him before the Medical Congress in 1876 were as follows:¹ —

I. "The virus of venereal sores is dual."

II. "Some venereal sores are due to the inoculation of the syphilitic virus."

III. "Other venereal sores are due to the products of simple inflammation."

IV. "These two poisons may be inoculated simultaneously."

It will be seen that this is a pretty radical stroke at the existing accepted ideas on venereal disease. According to it every venereal sore is either the result of syphilitic infection, that is to say, a primary syphilitic lesion, or the result of the products of simple inflammation. The chancreoid is wiped out, and does not exist. The data from which these conclusions were deduced are: (1) several observations from experimental inoculation by well-known observers, which show that a pustule can be produced by the inoculation of pus, and (2) to this the greatest importance is given, from the report of a series of inoculations made by Dr. E. Wigglesworth on himself during the year 1867-68, while finishing his medical education at Vienna. The object of this experiment was, to use Dr. Wigglesworth's words as quoted by Dr. Bumstead, to show that "*pus, pure and simple, might be the cause of the chancreoid.*" Dr. Wigglesworth inoculated with pus obtained from a pustule of acne on his arm, and obtained pustules, the pus of which he again inoculated with the same result, and carried the experiment one step farther successfully. The method of inoculation was by "pricking open the apertures of hair follicles and then rubbing the pus into them." The conclusion which he drew from these experiments was "that pus-products of inflammatory action, if properly introduced into the human integument, may cause local ulcers closely resembling chancreoids, and reinoculable in generations."

The discussion on Dr. Bumstead's paper was a most interesting one, and I regret that the limits of an article of this nature will not allow its reproduction, more especially the remarks made by Dr. E. L. Keyes. Dr. R. W. Taylor was the only delegate who indorsed Dr. Bumstead's conclusions, and he quoted two cases of his own as corroborating the inferences, which I will refer to later. In the introductory chapter on the History of Venereal Diseases in the new edition of Dr. Bumstead's work, which has recently come out, he says,² "The conclusions at which we have arrived may be summed up as follows: —

"I. The chancreoid is entirely distinct from syphilis.

"II. The chancreoid, however, does not depend upon a specific virus of its own, incapable of being generated *de novo*.

"III. The chancreoid in most cases met in practice is derived from a chancreoid, but it may arise, especially in persons debilitated by any cause, from inoculation of the products of inflammation, either sim-

¹ Transactions of the International Medical Congress, Philadelphia, 1877, page 714.

² Page 81.

ple or syphilitic, and subsequently perpetuate itself from one individual to another as a chancreoid."

I omit his fourth conclusion as to the mixed chancre, as it has no interest in this connection. On page 339 he says, "That it [the chancreoid] possesses a contagious element or poison is unquestionable, but we believe this poison, under certain conditions, and especially where the products of simple inflammation have undergone decomposition and are inoculated on persons in a debilitated state, *is capable* of being generated *de novo*, and may then be transmitted to other individuals. That such an occurrence is *frequent* in sexual intercourse we do not claim, and we expect to find a chancreoid in that person of the opposite sex with whom a patient applying to us with a chancreoid has had intercourse; but that it may and does take place, however rarely, the experiments above detailed appear to leave no doubt." It will be at once seen that this is a very different statement from that made in his paper, in 1876. There the chancreoid was ignored; all venereal sores were either syphilitic or the results of inflammatory pus. Now the chancreoid is accepted, described, and referred to almost exactly as in his previous editions, only he claims that it *may*, though rarely, be produced by any purulent inflammatory secretion.

The data from which he draws this conclusion in the new edition of his book are exactly the same as were mentioned in his paper, especial prominence being given again to the experiments of Dr. Wigglesworth, and in addition a case is reported by his collaborator, Dr. R. W. Taylor. What do Dr. Wigglesworth's observations amount to? — that by the inoculation of pus he produced a pustule? That pus corpuscles introduced into the cutis will cause suppuration is certainly nothing new; so will grains of sand, chips of steel, slivers of wood, or any other foreign substance, the resulting pustule being simply nature's process of expelling the offending source of irritation. In the case of pus corpuscles there are undoubtedly other factors for starting the suppurative action in the cutaneous tissues, beyond the mere presence of the pus corpuscles as foreign bodies. These are the possible carrying out of the function of the pus corpuscles, when introduced into living tissues, of multiplying themselves by proliferation, and the special irritant, septic, or chemical character belonging to pus as such. But whatever the causes may be, the fact that by the inoculation of pus into the cutis pustules may be produced is established by the experiments of many observers. A pustule of course is, when the epithelium covering is destroyed, an ulceration, but that this ulceration is a chancreoid is an assumption pure and simple. We have no history of the characteristic appearance of the chancreoid, nor of its course, nor of the peculiar accompanying glandular reaction. All that is stated is that pus inoculated has produced a pustule, and that is a fact which any one who ever experimented with the lancet must be aware of; only if he has been an intelligent experimenter he will have learned to recognize (after a certain lapse of time, perhaps) whether this pustule is the result of chancreoid pus, or of "simple inflammatory product."

It must be remembered that the history of the chancreoid, as we understand it, has been carved out, so to speak, by the point of the inoculating lancet in the hands of such men as Ricord, Diday, Rollet, Henry Lee, etc. They found that pus from a cer-

tain kind of ulcer called forth certain specific results which other pus did not. Now, to claim on the strength of one experiment by one observer that they were all wrong, and that any pus will produce these results, is certainly illogical, to put it in the mildest form. The observation of a single individual, not corroborated by others, must in science always be taken with caution. The temptation to see things as we want to see them, especially when the observer is young and enthusiastic, and is experimenting with the hope of getting certain results, cannot always be controlled.

Is it not strange that, nearly four years having elapsed since Dr. Bumstead first advanced the idea that the chancreoid might be the result of simple inflammatory product, neither he nor Dr. Wigglesworth, on whose observations he founds his theory, have any further corroborating experiments to bring forward, though they both of them, from their connection with hospitals and dispensaries, have had exceptional facilities for pursuing such investigations?

If the inoculation of inflammatory product may create chancreoids, why is it that out of the millions of cases of vaccination we have no record of chancreoids on the arm? Even admitting that pus on the point of the lancet may produce a sore which resembles the chancreoid, it does not by any means follow that such could be the result of contact with the same pus in sexual intercourse. Ward tenders, surgeons, medical students, nurses, etc., are constantly brought in contact with pus of all kinds; they do at times get angry, irritated ulcerations as a result, but nothing that is like a chancreoid, unless they come in contact with chancreoid pus. I am perfectly aware that negative evidence proves nothing, but nevertheless, having observed nearly fourteen thousand cases of skin and venereal disease at the Boston Dispensary, of which nearly fifty per cent. were venereal, besides a very fair number in private practice, and never having once had the generation *de novo* of a chancreoid suggested to me, these facts certainly would justify me in feeling that such an occurrence must be of great rarity at least. But it is with no idea of attempting to *disprove* the point at issue that I have taken pen in hand. The arguments that could be brought against it are so numerous and various that merely to refer to them all would swell this paper far beyond the limits of space for which I should feel justified in taxing the courtesy of the editors, especially on a subject which is not, perhaps, of much general interest. In such a question as this the burden of proof evidently is with the side that combats established facts, and all that I have felt called upon to show is that such proof is lacking.

Dr. Taylor's case is a very interesting one, and at first sight it does seem to show that a chancreoid can be generated *de novo*. He reports the case of a man who contracted gonorrhœa; during the acute stage he had a crop of herpetic vesicles on the prepuce; these vesicles, from the influence of the *gonorrhœal* pus, turned into chancreoids. The man got drunk, had connection with his wife, and infected her with chancreoids. He was, by the bye, syphilitic, having at the time a papular secondary eruption. It seems to me that it is perfectly fair, before accepting an observation as disproving what is generally recognized as an established truth, to require that it should not be capable of explanation in accordance with the

truth it is expected to confute. Now in this case all we have to suppose is that there may have been a urethral chancre, the secretion of which inoculated the herpetic vesicles; or that the wife had been untrue to her husband, as it is admitted that she was afterwards, had contracted chancroids, and had given them to him, instead of having been infected by him. Or even on general principles it might be urged that in a case of that sort, where a man had syphilis and gonorrhoea, got drunk, and had connection with his wife, who afterwards acquired syphilis from a third party, the morale of the patients was such that any history as to exposure or non-exposure was not to be relied on; especially when it conflicted with truths that had been worked out by years of patient and persistent industry by the best investigators in medical science.

It may seem that this is a matter of very small importance, but it is not. The more we investigate the subject of venereal disease, the more we are impressed with the wonderful constancy of the fundamental laws which nature or disease follows, and to claim that these laws may at rare intervals be entirely upset, and that the same results may be produced by entirely different causes, is striking at the foundation stone of the structure of medical science, and introduces an element of doubt and accident where, by slow and gradual steps, we are hoping to show a logical connection between cause and effect. That the data from which the conclusions are deduced are insufficient I have endeavored to show, and it certainly seems that until further corroborative testimony is advanced we should continue to regard the chancre as an existing fact, not to be confuted with irritated herpetic vesicles, inflamed follicles, or the sores resulting from the pricking of hair follicles with or without the subsequent application of pus. Certainly from the amount of evidence up to the present time advanced we can hardly consider the reference to this pathological fact as the "so called chancre," made in "E. W.'s" review of Bumstead in the *JOURNAL* of the 22d of January, as a justifiable one.

I cannot conclude without referring to the very great excellence of the result of Drs. Bumstead and Taylor's labors, as shown in the last edition of the former's treatise on venereal diseases. It is one of the best works on the general subject that has appeared in any language, and will undoubtedly meet with even more success than its preceding editions in being translated for the benefit of foreign science. Its great merit lies in its usefulness as the means of instruction or for the purpose of reference, the fundamental truths being stated in a clear and concise manner, and the exploded theories (of which, alas, there are only too many) being referred to sufficiently to give the student a very clear idea of the important controversies that have been settled and laid upon the shelf, without confusing his mind with a mass of contradictory testimony, only to be grasped in order to be confuted. It is this very excellence as a text-book that has led me to protest against what seems to me a flaw in the otherwise perfect brilliancy of the work. I believe that Dr. Bumstead's accepting the theory in question is due to two marked mental characteristics, estimable and much to be envied in themselves, but liable to cause the possessor of them to go a little further than is justified by facts. Unless I am much mistaken, Dr. Bumstead's mind, without being radical, was progressive to such an extent that anything that

looked like a new truth was *a priori* regarded with favor. Also, I believe that his desire to give other investigators their full due led him to accept their conclusions, taking for granted that the same amount of careful, cautious, and unbiased investigation had been used in deducing them as would have been the case if he himself had been the investigator. That I am not mistaken in this is, I think, shown by the position he has taken on the subject of syphilization. It happened to be my good fortune to be in New York at or shortly after the time that Professor Boeck, of Christiania, was there, and to visit the venereal wards at Blackwell's Island with Dr. Bumstead. He had allowed Professor Boeck to carry on and superintend a series of very complete experiments there, and although to his logical mind the claims of the advocates of syphilization were unfounded, the enthusiasm of that eminent though mistaken investigator impressed him to such an extent that in his edition previous to the present one (1870) he devoted a chapter of sixteen pages to the subject, in which, while not in any way indorsing the doctrines of that school, he still left it rather an open question as to whether there might not be something in the matter worthy of further investigation. In the present edition the subject is dismissed as an illogical absurdity, in the space of half a page, and such, I am convinced, would have been the fate of the theory that a chancre might be generated by any inflammatory product, had been spared for a few more years to medical science.

THE FUTURE OF WOMAN.

MR. EDITOR.—For some time I have read the journal published under your management, and truth compels me to add with very little profit. My aspirations are towards the rose-colored future; but with an iron chain you would fetter me to the cold, dreary past. Still I am not hopeless. There is a light in the East. See what was said to-day at the meeting of our noble Massachusetts Woman Suffrage Association! See, too, who said it! A young gentleman from Harvard College. I do not ask you to trust me; here it is in to-day's *Transcript*:—

"Mr. Burton M. Firman, a young gentleman from Harvard College, thought that the generation that was growing up would largely favor the movement; he knew many young men who were ready to urge the measure, and who would vote for it if the chance were ever given them. It was absurd to say that the natural condition of woman was against it. How did any one know what was her natural condition? She was now what generations of repression and false teaching had made her. He had no doubt that in looking back to this time future generations would wonder that society could have had such narrow views as to deprive woman of what was her right."

What originality of thought! What vigor of expression! Happy will be the day when he and those other young men shall study medicine and begin by reforming their future profession. Who knows, Mr. Editor, but that we shall be there too? Then, instead of dry facts, our society shall echo and reecho with flights of fancy like that of this gallant young gentleman from Harvard. But where will you be then, Mr. Editor? Yours tauntingly, ROSA MATILDA.

Boston, January 29, 1880.

REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 31, 1880.

Cities.	Population estimated for July, 1879.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Total Deaths from				
				The Principal "Zymotic" Diseases.	Lung Diseases.	Diphtheria and Croup.	Scarlet Fever.	Typhoid Fever.

Two thousand three hundred and twenty-four deaths were reported; 892 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 467, consumption 357, lung diseases 280, diphtheria and croup 204, scarlet fever 86, whooping-cough 36, measles 33, diarrheal diseases 32, typhoid fever 30, erysipelas 17, malarial fevers 16, cerebro-spinal meningitis nine, small-pox four.

From whooping-cough, New York eight, Brooklyn five, Boston four, Philadelphia and Cincinnati three, Chicago, Baltimore, New Orleans, Pittsburgh, and Chicopee two, St. Louis, Cleveland, and Fitchburg one. From measles, New York 23, Chicago four, Brooklyn three, Philadelphia, St. Louis, and Holyoke one. From erysipelas, New York seven, Philadelphia two, Brooklyn, Chicago, St. Louis, Pittsburg, Milwaukee, Lawrence, Somerville, and Milford one. From malarial fevers, New York eight, St. Louis three, New Orleans two, Brooklyn, Chicago, and Baltimore one. From cerebro-spinal meningitis, New York three, Philadelphia, Chicago, Worcester, Fall River, Chelsea, and Northampton one. From small-pox, Philadelphia and District of Columbia two; one case was reported in Baltimore. Sixty-six cases of measles, 50 of diphtheria, and 37 of scarlet fever were reported in Brooklyn; diphtheria 47, scarlet fever 16, in Boston; scarlet fever 12, diphtheria eight, in New Bedford. Scarlet fever is declining in Cleveland. The death-rate of whites in the District of Columbia was 15.05, of colored 26.93.

The total number of deaths was nearly the same as for the previous weeks, of deaths under five somewhat less. Measles, small-pox, lung diseases, and consumption caused fewer deaths. In 37 cities and towns of Massachusetts, with an estimated population of 1,021,110 (population of the State about 1,690,000), the death-rate was 20.17 against 20.58 and 20.89 of the

previous two weeks, the mortality from diphtheria, scarlet fever, and measles showing a decline.

For the week ending January 10th, in 143 German cities and towns, with an estimated population of 7,550,717, the death-rate was 27.7 against 27.2 and 27.5 of the previous two weeks. Three thousand seven hundred and ninety-two deaths were reported; 1704 under five: pulmonary consumption 520; acute diseases of the respiratory organs 476, diphtheria and croup 153, scarlet fever 66, measles and *rötheln* 60, typhoid fever 56, whooping-cough 45, purperal fever 20, typhus fever one, small-pox none. The death-rates ranged from 16.7 in Bremen to 36.6 in Strasburg; Königsberg 21.9; Dantzig 24.7; Breslau 26.2; Munich 32.8; Nuremberg 19.2; Dresden 26.3; Berlin 25.2; Leipzig 27.5; Hamburg 31.5; Hanover 20.3; Cologne 25.2; Frankfurt 22.3. For the same week, Vienna 30.5; Prague 41.0; Paris 28.1. Small-pox continues very prevalent in Paris and Bucharest; less so in Vienna, Prague, St. Petersburg, Warsaw, Odessa, Venice, Barcelona, and Alexandria.

For the week ending January 17th, in the 20 English cities and towns, with an estimated population of 7,383,999, the death-rate was 21.2 against 24.0 and 29.1 of the previous two weeks. Three thousand four hundred and eighty-four deaths were reported: diseases of the respiratory organs 512, whooping-cough 164, scarlet fever 143, measles 123, diarrhoea 34, fever 31, diphtheria 19, small-pox (London) four, showing an increase in lung diseases and scarlet fever, and a diminution in whooping-cough, diphtheria, measles, fever, and diarrhoea. The death-rates ranged from 16.0 in Brighton to 28.1 in Liverpool; London 24.6; Bristol 16.9; Birmingham 25.1; Leicester 18.1; Manchester 27.6; Leeds 17.3. In Edinburgh 18, Glasgow 24, Dublin (small-pox seven deaths) 38.

The meteorological record for the week in Boston was as follows:—

SIXTH DECENNIAL PHARMACOPOEIA CONVENTION.

By virtue of authority developed upon me as the last surviving officer of the Pharmacopoeia Convention of 1870, I again call the attention of "the several incorporated state medical societies, the incorporated medical colleges, the incorporated colleges of physicians and surgeons, and the incorporated colleges of pharmacy throughout the United States" to the importance of appointing delegates to the sixth decennial pharmacopoeia convention, and of sending the names and residences of the same to me for publication. The convention meets on the first Wednesday in May, 1880, and I am required "to publish the names and residences of the delegates, for the information of the medical public, previous to its meeting."

I have received so far the names and residences of the following delegates:

From the Massachusetts College of Pharmacy, Boston: Prof. G. F. H. Markoe, Ph. G.; Samuel A. D. Sheppard, Ph. G.; Thomas Dolber, Ph. G.

From the Philadelphia College of Pharmacy: Prof. John M. Maesch, Alfred B. Taylor, Prof. Jos. P. Remington.

From the Louisville College of Pharmacy: Prof. Emil Scheffer, Prof. C. Lewis Diehl, E. Vincent Davis.

From the Maryland College of Pharmacy, Baltimore, Md.: Delegates, Wm. S. Thompson, Louis Dohme, Jos. Roberts, Alternates, Charles Caspari, Jr., Dr. John F. Moore, Dr. Robert Lautenbach.

From the Medical Society of the District of Columbia: Prof. D. W. Prentiss, M. D.; Prof. Thomas Antisell, M. D.; Emeritus Prof. James E. Morgan, M. D.

From the National Medical College of Columbia University, Washington, D. C.: Prof. W. W. Johnston, M. D., Prof. D. W. Prentiss, M. D.

From the Medical Department of the University of Georgetown, D. C.: Prof. W. H. Ross, M. D., Prof. C. H. Klein-schmidt, M. D.

From the National College of Pharmacy, Washington, D. C.: Mr. W. S. Thompson, Prof. Oscar Oldberg, Mr. R. B. Ferguson.

(Signed,) JAMES E. MORGAN, M. D.

WASHINGTON, D.C., January 28, 1880.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JANUARY 31, 1880, TO FEBRUARY 6, 1880.

DE HANNE, J. V., captain and assistant surgeon. Granted leave of absence until further orders, on account of sickness, to take effect February 1, 1880. S. O. 26, A. G. O., February 3, 1880.

BYRNE, C. B., captain and assistant surgeon. The leave of absence granted him December 20, 1879, from A. G. O., extended four months.

CRIVELLO, T. A., first lieutenant and assistant surgeon. Granted leave of absence for one month, with permission to apply for one month's extension. S. O. 11, Department of Dakota, January 26, 1880.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting will be held Monday evening, February 16th, at eight o'clock, at 19 Boylston Place. Reader, Dr. Cowles. Subject, Non-restraint in English and Scotch Asylums for the Insane. FREDERICK C. SHATTUCK, M. D., Secretary.

SUFFOLK DISTRICT MEDICAL SOCIETY. — The society will meet at 19 Boylston Place, Saturday, February 14th, at seven and a half o'clock. Papers will be read by Dr. F. A. Harris on Society Work and by Dr. E. Cutter on the Salubrious Treatment of Consumption. The proposed act to regulate the practice of medicine will again be brought before the society for discussion. All members of the Massachusetts Medical Society are cordially invited to be present and take part in the proceedings.

BOOKS AND PAMPHLETS RECEIVED. — The Student's Guide to Diseases of the Eye. By Edward Nettleship, F. R. C. S., Ophthalmic Surgeon to St. Thomas's Hospital. Philadelphia: Henry C. Lea. 1880.

Clinical Lectures on the Diseases of Women, delivered in St. Bartholomew's Hospital. By J. Matthews Duncan, M. D., LL. D., F. R. S. E. Philadelphia: Henry C. Lea. 1880.

Annals of the Anatomical and Surgical Society. Vol. I. 1878-79. Brooklyn 1879.

Salisbury's New Physical Signs of Syphilis. By Ephraim Cutter, M. D. (Reprint) 1879.

The Pathology of Mind. Being the Third Edition of the Second Part of the Physiology and Pathology of Mind, recast, enlarged, and rewritten. By Henry Mandesley, M. D. New York: D. Appleton & Co. 1880.

The Answer of the New York Neurological Society to the Document known as the Report of the Committee on Public Health relative to Lunatic Asylums. New York. 1880.

The Chemistry of Common Life. By the late James F. W. Johnston, M. A., F. R. S. S., L. D. and E., etc., Professor of Chemistry in the University of Durham. A New Edition, revised and brought down to the present time, by Arthur Herbert Church, M. A. Oxon. New York: D. Appleton & Co. 1880.

A System of Medicine. Edited by J. Russell Reynolds, M. D., F. R. S. With numerous Additions and Illustrations, by Henry Hartsorn, A. M., M. D. In three volumes. Vol. I. General Diseases and Diseases of the Nervous System. Vol. II. Diseases of the Respiratory and Circulatory Systems. Philadelphia: Henry C. Lea. 1879. (Subscriptions received by Mr. French, agent, who will soon visit physicians in this neighborhood.)

Transactions of the Medical Association of the State of Missouri. 1879.

Lectures.

CLINICAL LECTURE, WITH REMARKS, UPON A CASE OF TYPHOID FEVER AND THE SO-CALLED SPECIFIC TREATMENT.

DELIVERED AT THE JEFFERSON MEDICAL COLLEGE HOSPITAL, PHILADELPHIA.

BY PROFESSOR ROBERTS BARTHOLOW, M. D.

GENTLEMEN, — The first patient brought in this morning will be the case of ambulant typhoid which was presented to you a week ago. As I told you then, such cases are rather rare. When we saw him at that time, it was the case of a man going about suffering from inflammation and ulceration of the glandular patches in the small intestine near its termination, which are the characteristic lesions of typhoid. The risk is so great in these ambulant cases that we could not allow the patient to continue going about; perforation and peritonitis would be liable to occur, and a fatal issue would naturally result. He was put to bed, and since then he has exhibited the characteristic fever of a remittent type, which we recognize as typhoid fever. The fever of typhoid is said to be of the continued type, but it is so only relatively, not absolutely. In health, as you know, there is a daily fluctuation in the bodily temperature, which attains its maximum in the early evening and its minimum in the early morning hours. The fever of typhoid shows the same variations, — an evening exacerbation and morning remission. During the first week of the fever the morning decline is exceeded by the evening rise until the maximum is attained in the second week, towards the end of which we observe the morning remissions becoming more marked, until the temperature returns to the normal in the fourth week.

Upon the day of admission this man's temperature was 104° F. in the evening. You remember I told you that if the temperature did not go above 102° F. we would not interfere, but if it rose above this point we would rely upon a full dose of quinine for an antipyretic action. The resident physician very properly gave him twenty grains that evening with decided effect. Now the excursions of the temperature record are less, — as it is the third week, — preparatory to convalescence, which is nearly at hand. He has only two evacuations per diem; his tongue is cleaning, although still raw and glazed, and the hebetude is passing away. You must be struck with the improved expression and intelligent appearance of his countenance; and you notice that his mental condition is brighter than at the beginning.

There was a plentiful crop of the peculiar rose-colored erythematous eruption of typhoid. It is now disappearing, but still can be recognized. The distention of the abdomen and gurgling in the right iliac region are also less. Notwithstanding the diminution of the gurgling there is still some tenderness, and our patient is not yet free from danger. Notwithstanding the fact that it was a mild case, there may ensue a perforation of the intestine with serious results; we shall therefore still carefully attend to his diet, and keep him strictly in bed. While these ulcers of the intestine are only partially healed, if he were careless and ate indigestible food, a sudden development of flatus might distend the bowel, and cause a rupture and fatal collapse or peritonitis. This accident may occur both in

light and in grave cases of typhoid fever, but it is a remarkable fact that perforation is more liable to take place in the ambulant cases than in the severer forms, and may be produced by a single apparently insignificant ulcer in the intestine. We should therefore always insist upon these precautions as to rest and diet in each individual instance of typhoid fever, although it may not be a very marked case of the disease.

In regard to the treatment, I have told you that when the temperature rose we gave him a full dose of quinine with the desired antipyretic effect. He has had the so-called specific treatment of Lugol's solution, five drops three times a day, well diluted. Upon this he has done very well. I pointed out, in the previous discussion of the case, that there were two main points in the mode of treatment, termed by the Germans the specific treatment for typhoid fever: calomel given early in the disease in ten-grain doses for three or four days during the first week of the disease; and the administration of iodine, either in the form of tincture or Lugol's solution. The latter form is preferable, and it is that which this patient has been taking.

From experience in other cases I consider the above method certainly an advance in the treatment of typhoid fever. It is not termed specific on account of any supposed influence it has directly upon the typhoid fever, but from the power of the iodine to destroy the germs of the disease in the discharges of the intestinal canal, on account of its well-known antiseptic properties. The propagation of typhoid is due to a peculiar *matres morbi*, which is supposed to be in the alvine discharges, and which subsequently finds its way into our bodies with our food or drink, or even through the inspired air, and there reproduces the disease. The mode of action of iodine upon these ferments has led to the supposition that it would be a useful agent in the treatment of typhoid, and experience has confirmed this view.

POSTERIOR SPINAL SCLEROSIS.

As this man walks into the arena, notice his peculiar method of locomotion. Observe his gait, the manner he has of swinging his foot around, describing a semi-circle, bringing his heel down with considerable force; he treads with weight, making some noise in walking. This affection gives a man rather an imposing gait, unless the difficulty is very far advanced.

Now, from the inspection of the man's gait, who will make a diagnosis of the case?

Let us note his history. The disease has existed for a long period, at least five years, and it was preceded and subsequently accompanied by acute neuralgic pains in the lower extremities, which he describes quite correctly as "lightning pains shooting down the legs." He also complains of a feeling of pressure or stiffness in the muscles of the calf; he has not noticed the sensation of a constriction tightly around his limbs, like a cuirass closely binding them, as is sometimes experienced in these cases. He has decided disturbances of sensibility in the lower extremities, especially a marked degree of numbness. To determine the physical condition of the parts, we will now have the limbs stripped, and apply certain tests to ascertain whether we shall obtain the normal reactions or not. We shall follow certain methods to determine accurately the condition of the muscular and other parts of the limb, and, indirectly, the general nervous system, to see if it shares in the affection. What are these methods?

In the first place, we test the power of motion; interrogating the muscles to see if their mobility is impaired, and if so in what respect. This point we shall now ascertain. You have noticed that in walking he moves the limbs abnormally, and we ask, Is this because they are weak, or is it simply disordered motion?

As he lies on his back, now, he kicks with vigor, although the movements are badly directed. As I now grasp his leg, with the knee partially flexed, I find that he uses considerable power in attempting to extend the limb; there is no muscular paralysis. The trouble in walking is therefore not due to want of muscular power, but to want of coordination in the muscles, which makes his movements appear awkward. This loss of coordination is observed even when he directs his attention to his efforts, but when his attention is called off, or his eyes are shut, the condition becomes more marked; therefore we say that both voluntary and automatic coordination are disordered. I have pointed out to you that the mechanism in walking is partly automatic and partly volitional. In ordinary walking we are not conscious of any effort in using the muscles, but our attention is free for other objects, while the muscles regularly and rhythmically perform their functions, deriving their innervation from the spinal cord; these movements are automatic. If I should take up a pen to write, and there happened to be want of coordination of the muscles, I would be unable to write intelligibly; the voluntary action would be affected, while the brain (apart from the special cortical centre for written language) would be intact. Applying our test to the patient, we find that if we talk to him while he walks he cannot walk well, but staggers; but when he directs his attention to the effort he is making he can walk better.

In order to walk with success, it is essential that sensibility should be unaffected, so that we can feel the resistance of the ground, or the surface we walk upon; we must be conscious of the feet pressing upon the ground. If this is imperfect, our movements are disordered. Therefore it is that plantar anesthesia plays a large and important part in the troubles under discussion. We find that ordinary tactile sensibility, sensibility to heat and cold, and perception of pain — which are entirely distinct properties of sensory nerves — are not always equally affected. Let us first try the sense of touch, for which we use the aesthesiometer, a pair of compasses with sharp points. At the same time that we ascertain the accuracy of his tactile impressions, we will also learn the rate at which impressions are transmitted to the cerebral centres. You know that even in health we do not perceive peripheral impressions immediately; it is only apparently so, although we think we recognize them at once. In this case, asking him to tell us when I touch his foot with the point of the compasses, you notice that the transmission of impressions is delayed; they take a longer time than in health to reach the brain. There is a perceptible interval between touching the surface and his perceiving it; we may say, therefore, that the transmission of tactile impressions from the surface to the centre is retarded. Now try his ability to distinguish heat from cold. Applying in succession hot and cold sponges, we find that he faithfully interprets temperature, as he is correct in his replies; he can distinguish heat from cold. Testing his appreciation of pain by pricking him with the points of the aesthesiometer, we learn

that there is actually less numbness in the plantar surface than in the legs, although the perception of pain is sensibly impaired in both regions.

With the aesthesiometer two points are felt as one, one and one half inches apart on the dorsum of foot; on the leg they are felt as one at two inches; so that the tactile sense is impaired, but not abolished. Sensibility to touch, pain, temperature, we may therefore say is present, but is impaired.

This examination changes to some extent my opinion of the locality of the lesion in the spinal cord. I was disposed at first to locate the disease in the antero-lateral region, but as the disorder is mainly that of coordination the lesion must be located farther back, and mainly in the posterior columns.

His difficulty in walking is not so much due to the want of sensibility in the plantar surface, which at first suggested itself as the explanation, as to the marked want of coordination in the muscles concerned.

The electrical examination is necessary to complete our study of the case. You see the muscles respond perfectly to the faradic current, and contract energetically to a moderate current.

In the early stage of posterior spinal sclerosis, you remember that the disorder, as a rule, manifests itself first in the lower extremities, and afterwards extends to the arms in the second stage, or, in the opinion of some writers, in the third stage. Our patient has no trouble in his upper extremities; he can use his knife and fork in eating, and button his clothes without difficulty. We infer that the disease is in its first stage, and has not involved the upper part of the spinal cord. What confirms our opinion as to the diagnosis and the localization of the affection in the lower part of the cord is the fact that the sexual functions are recently impaired; he has not had an erection for some time, and lately has had some nocturnal seminal losses. This sexual impairment generally belongs to the early symptoms, and usually precedes, rather than follows, disturbances of motility.

The disease is therefore still limited to the lower part of the spinal cord, and as the power of coordination resides in the posterior part of the structure we conclude that it involves mainly the posterior columns, making it a case of posterior spinal sclerosis, which now explains fully the attacks of fulminant pains that have so long annoyed him.

In considering the question of treatment, we find a general agreement of opinion among authorities that, as regards therapeutics, the condition is not encouraging. No one will dispute this who has had anything to do with the disease. The best results obtainable — palliation of symptoms and the arrest of the disease — are perhaps secured more satisfactorily with phosphorus than anything else. It should be given for a long time and in small doses (about one hundredth of a grain), for which cod-liver oil is a good vehicle. Some curative results have been obtained by this treatment. In order to maintain the nutrition of the parts affected, a weak continued current should be applied from the spine to the lower extremities; although this will have no effect upon the disease, it will materially relieve the pain. He shall therefore have the constant current daily, in conjunction with the internal administration of phosphorus dissolved in cod-liver oil, of which he should take a teaspoonful, containing one hundredth of a grain of phosphorus, three times daily, after meals.

RECENT PROGRESS IN THE TREATMENT OF THORACIC DISEASES.¹

BY F. I. KNIGHT, M. D.

Berkart on Asthma (concluded).—In the chapter on the treatment of asthma the author says that so long as the asthmatic tendency was supposed to be a mysterious derangement of the nervous system, there could obviously be no question as to the prevention of the disease; but, according to the view by him adopted of its nature, an efficient prophylaxis, though, for various reasons, impracticable in some cases, appears by no means so in all of them. On the contrary, the fact that in the vast majority of instances asthma is traceable to pneumonia, whooping-cough, and measles affords just grounds for assuming that by timely subduing the catarrhal inflammation the subsequent disposition to the dyspneal seizures may be completely averted or greatly diminished. Whether this assumption will prove correct or not is a matter of future observation. Meanwhile, although every case of catarrhal pneumonia is not necessarily developed into asthma, still, as this so often appears to be the consequence of the former, it is no superfluous prevention to guard against the contingency. The precautionary measures required for the purpose merely consist in the judicious management of those affections in which the inflammation of the bronchi has a tendency to spread to the parenchyma of the lungs.

When asthma has declared itself there are, as a rule, changes of the pulmonary tissues, which vary in nature and extent in different cases. But though those changes do not always betray themselves by adequate physical signs, they are, notwithstanding their latency or seeming insignificance, essentially the disease, and no plan of treatment, unless in the first place and specially directed to them, can be productive of permanent benefit. Indeed, the proverbial intractability of asthma is mainly due to the exclusive attention hitherto bestowed upon the dyspneal paroxysms, at the expense of the organic lesions from which they arise. No amount of attention to the exciting causes will protect against the attacks of asthma unless the morbid susceptibility to them be simultaneously diminished. Thus the treatment of asthma aims at arresting the progress of the existing pathological changes, and at maintaining the healthy portions of the lungs in a state of greatest efficiency. These objects are quite attainable in most cases, partly by improving the nutrition of the organism and indirectly that of the lungs, partly by restoring the normal function of the bronchial surface.

Directions concerning hygienic measures should be at least as definite as those that are usually given with regard to the purely medicinal treatment. Foremost among them is the constant supply of pure air. Not only the impairment of nutrition, but in many instances the nocturnal attacks of dyspnoea are due to an imperfect supply of pure air at night. But if patients have lived for a length of time in a confined atmosphere their bronchial mucous membrane generally is in a state of anesthesia from the narcotic influence of the carbonic acid, but as, on exposure to a

purser atmosphere, that membrane recovers part of its sensibility, cough is now readily induced by the irritating substances contained in the air. Such return of the bronchial sensibility, however, is usually regarded, not as a favorable sign, but as a "fresh cold." The patients therefore refuse to continue the treatment, and immediately return to narcotics in order to suppress the cough. Hence, the longer they have breathed in a vitiated atmosphere, the more gradually are their habits to be changed. In the summer and autumn it may be necessary for such patients to sojourn at the sea side or on a small island, on account of the dyspnoea which the pollen and spores of the fungi floating in the atmosphere are likely to produce. A yacht cruise answers this purpose especially well. In the winter asthmatics should live at places where the genial climate and beauty of the scenery both permit and attract them to spend the greater part of the day in the open air.

The systematic employment of warm baths at a temperature of from 95° F. to 102° F. has a direct curative influence upon asthma. By no other means than this is it possible so effectually to relieve the lungs of the chronic congestion, with its abundant exudation of white blood corpuscles which choke up the bronchi. Chronic gastric catarrh, if it exists, must be treated upon known principles. In regard to the medicinal treatment, the author says that among the numerous remedies that have been recommended for the treatment of asthma, the great majority are narcotics or so-called nerve tonics, intended to allay the supposed morbid irritability of the centre of respiration. But apart from the uncertainty of their operation, even in the hands of those who most loudly proclaim their virtues, their prolonged exhibition is not indicated by the nature of the disease, nor has experience shown them to be productive of more than a transient benefit. The medicinal agents which in certain cases appear to be useful are: (1.) *Arsenic*. This is indicated for the relief of the dyspepsia of asthmatics, and for the improvement of their nutrition, provided that the alimentary canal is free from inflammatory affections, and the action of the heart is not too feeble. In cases in which asthma is due to compression of the air tubes by enlargement of the bronchial glands, arsenic may be cautiously tried. The dose of this drug should be gradually increased, the patient being carefully watched, its maximum being reached in fourteen days, and it being suspended at once if signs of poisoning appear. (2.) *Alkalies*. In the cases in which viscid mucus occludes a number of bronchioles so as to impede the access of air to the lungs, the means previously mentioned as intended to reduce the disposition to asthma remain ineffectual, in consequence of the imperfect oxygenation of the blood. Under these circumstances alkalies may be usefully given, with the view of removing the existing obstacle to respiration, and of modifying the secretory function of the bronchial mucous membrane. As in such case the alkalies have to be continued for a length of time, the salts of soda are preferable, because they are better borne by the stomach than those of potash. They are best given in the shape of a mineral water, such as Ems, Wiesbaden, Kissingen, Vichy, etc. Iodide of potassium, which forms the base of Aubré's well-known specific [also of Jonas Whitcomb's], was first given in asthma by Horace Green. It has all the properties of an alkali, and possesses, moreover, as Heubel sup-

¹ Concluded from page 154.

poses, a special affinity to the pulmonary tissue. Its administration in suitable cases is always attended by the best results. The dose varies from five to ten grains several times a day. [Dr. J. P. Oliver, of this city, has recently introduced, with surprisingly satisfactory results, the plan of gradually increasing the dose of iodide of potassium up to fifty or sixty grains, and continuing it for a long time. He warns against expecting relief too soon, and informs the patient that he may not notice any change during the first six weeks.] It should be freely diluted, and taken upon an empty stomach. Iodide of potassium is inapplicable, however, when the bronchial mucous membrane is in a state of acute inflammation. For, in contact with the atmosphere, the iodine is disengaged from its combination with the albumen of the blood, and when thus set free it is apt to irritate the surface of the air tubes, and to produce here an analogous process, as it does upon the skin and the nasal mucous membrane. Chlorate of potash also may be advantageously given.

The balsams and sulphur occupy a doubtful place in the treatment of the asthmatic tendency.

The mechanical treatment of the respiratory tract greatly assists, so far as it is practicable, the various constitutional remedies. Its effective operation, however, is almost entirely limited to: (1.) *The mucous membrane of the nose.* This part of the air-passages demands more attention than it has hitherto received in the management of asthma, for there is little doubt that the permeability of the nasal canal is necessary for the due performance of the respiratory function and for the protection of the respiratory surface. (2.) *The bronchi.* The deep inspirations which patients are directed to take whilst inhaling (the gymnastics) are, no doubt, most beneficial to those who do everything for the cure of their dyspnoea but breathe properly. (3.) *The respiratory surface.* Inhalation of compressed air, in chambers specially prepared for the purpose, is greatly appreciated by the patients who have tried it. As to the manner in which condensed air acts nothing is definitely known. The question is as yet of little practical importance, for, besides being costly and within reach of but a few, the remedy has avowedly only a palliative effect. The inhalation of, or rather the expiration into, rarefied air in cases of emphysema appears to be more practicable on account of the greater simplicity of the instruments employed for the purpose. But inasmuch as the author is convinced that even the most extensive emphysema is, as such, not productive of dyspnoea, but that this, if present, is always due either to hyperæmia, or to inflammation of the mucous membrane, or to obstruction of the bronchi, he hesitates to attribute the relief which he observed in several cases to the use of the apparatus, and calls attention to the fact that Waldenburg in the cases reported as cured or relieved by its use employed also inhalations of chloride of sodium and of turpentine, together with the internal administration of arsenic.

The treatment of the paroxysm necessarily varies according to the nature of each case, so that an accurate diagnosis is the first condition of success. The prodromal symptoms, where such exist, afford valuable indications, by acting upon which the attack may either be prevented or promptly relieved. Thus there are on record numerous instances in which, upon the appearance of the signs peculiar to carbonic-acid intoxication, as headache, vertigo, fretfulness of temper,

and pain in the muscles, an efficient ventilation of the lung — by walking, driving, riding on horseback, etc. — successfully averted the threatening, and completely cured the fully developed dyspnoea.

Frequently, however, the precursory phenomena are either wanting, or are not so conspicuous. In that case, if the diagnosis remain doubtful, the treatment is necessarily deprived of its reliable basis. The removal of any known exciting cause, as of irritating gases, will usually cause the hyperæmia of the bronchial mucous membrane to subside. Hot and strong coffee, however, prove occasionally very useful when the energy of the heart is temporarily weakened by an excess of carbonic acid in the blood. The dyspnoea produced by a loaded condition of the stomach or of the rectum is speedily relieved by an emetic or an enema. If the offending substances cannot be at once removed by either of these means there is often a flatulent distention of the intestines that resists for a time all possible treatment. The best results are then obtained by small doses of creosote in camphor or cinnamon water. The fluxionary hyperæmia or inflammation of the bronchi, that arises from the inhalation of dust, can be subdued only by the removal of the irritants. This is often a matter of great difficulty. The dyspnoea may thus last for days, or even longer, until the particles of dust are detached from the bronchial surface by a copious exudation of serum. What is wanted is a rinsing, as it were, of the bronchial surface. Alkalies, although they increase the bronchial secretion, are yet too slow in their action. Copious draughts of warm water would best answer the purpose, but it is preferable to give hot infusions of *flos sambuci* or of senega root, to which acetate or carbonate of ammonia may be added. Jaborandi has been recommended, and, considering its physiological action, deserves a trial in asthma produced by the inhalation of foreign bodies. It is difficult to persuade the patient to take the drug a second time, on account of the very unpleasant effects which accompany its administration. Ipecacuanha, tartar emetic, lobelia, the smoking of tobacco and stramonium, act by producing arterial pressure and consequent increase of the serous exudation. In case of obstruction of the bronchi by viscid sputa the principles of treatment just alluded to are also applicable. The plugs of mucus are practically foreign bodies, the displacement of which is alone capable of procuring relief. Inhalations of salt lime-water, chloride of ammonium, fumes of burning nitre paper, and oil of turpentine sometimes give relief. Dyspnoea interferes with efficient inhalations. Then iodide of potassium in large doses and strongly diluted produces the desired bronchorrhœa, and its exhibition is indicated in the absence of an acute inflammatory process. In the cases in which the rhonchi, by their changes of site, show the mobility of the plugs, emetics are useful, since the compression of the thorax in the act of vomiting serves to remove the bronchial obstruction. Subcutaneous injections of apomorphia afford speedy relief, and, in the presence of cyanosis, they are preferable to the internal administration of drugs of a similar kind. Gerhardt recommends the manual compression of the bases of the lungs. This should be gentle, and made at the end of each expiration, but it should not be continued too long, lest it produce bronchial hæmorrhage.

In cases of embolism of the pulmonary artery stimulants may be required. Nitrite of amyl, which paralyzes the cutaneous vessels, and in small doses stim-

ulates respiration, may be cautiously tried in cases of pulmonary œdema.

In regard to the symptomatic indication, the author says, if the paroxysm be protracted and severe the relief of the symptom dyspnoea becomes the paramount object of the treatment. That object, however, can be obtained only by suppressing the irritability of the nervous system; and in attempting to do so it is well to remember that, desirable as a speedy relief is, it is yet not purchased without, at the same time incurring considerable risk. Instances are not wanting in which such purely symptomatic treatment has led to consequences more painful and also more serious than the disease itself is capable of producing (that is, the habitual ingestion of narcotics). Among the remedies most frequently used for the purpose of reducing the irritability of the respiratory centre are chloroform, chloral, and morphia.

The Antiseptic Treatment of Empyema.—It seems as if a great advance had been made in the radical treatment of empyema by operating and changing the dressing under the antiseptic spray. In the JOURNAL for January 29th is the report of an interesting clinical lecture, by Mr. Lister, on this subject. Fraentzel, in the first edition of Ziemssen's Cyclopaedia, strongly recommended this method, and gave results in eleven patients operated on by him. In the second edition of his article, published in 1877, he gives statistics in regard to twenty-two patients operated upon in this way. In eleven there was complete cure; that is, the patients were discharged without any noticeable deformity of the chest and without thoracic fistulae. In two of these cured cases the exudation had been fetid, and in two there had been a fetid pyo-pneumothorax, which had evidently arisen from pulmonary gangrene. The operations on these eleven successful cases were done from the third to the fourteenth week. Of the other eleven cases, three from whom the canula was removed too soon, and in whom the strict after-treatment was partially thwarted by their unreasonable resistance, were discharged with fistulae incompletely healed. Eight died not long after the operation: three with sanious exudation in the pleural cavities, from severe tubercular pleuritis and circumscribed caseous deposits in both lungs; one, in whom there existed at the time of the operation amyloid degeneration of the kidneys and a thoracic fistula, and from whom a piece of rib was taken at the time of the radical operation, died of secondary peritonitis; a fifth, in whom the purulent pleuritis had come on during the convalescence from a severe typhoid fever, of an acute pneumonia in the lower parts of the uncompressed lungs, which probably arose from taking cold during the operation; the sixth patient, in whom a pyo-pneumothorax had developed in the course of a caseous pneumonia, died of dysentery, which came on the day after the operation, and which was endemic in the hospital at the time; to the same disease another patient succumbed, in whom the autopsy showed that a cure would, in all probability, have taken place, and also showed that the pulmonary pleura and also the lung tissue superficially had been wounded by the catheter; in the eighth patient, three weeks after the operation, from some unknown cause, an interstitial nephritis developed, of which, at the end of another four weeks, the patient died. It will be seen that some of these patients died from purely accidental complications, and that others were in a hopeless condition before the operation.

Fraentzel has concluded in the future to abstain from the radical operation in case of purulent exudation in consumptive patients. Three such patients operated upon by him did badly, inasmuch as they quickly succumbed to fresh extensive tubercular inflammation in the opened pleura, with ichorization of the pleural contents, which was not affected by the most careful antiseptic procedure. In such cases, when there is severe dyspnoea and the pulse is small and frequent, or when, without these symptoms, the exudation is evidently very large, he aspirates and removes, at the most, eight to ten hundred centimetres at a time. He believes that in this way the patient's life is more prolonged than by the radical operation.

Fraentzel operates very differently from Lister, in that he washes out the pleural cavity not only at the time of making the opening, but afterwards, and Lister says any washing out is unnecessary. It would seem as if washing out at the time of opening the chest at least, were necessary, inasmuch as "shreds of fibrine, small or large, sometimes the length of one's hand, thickly infiltrated with pus corpuscles, having been washed out of the dependent parts of the pleural cavity, make their way into the wound, and are to be carefully removed." At the time of the operation and for two days afterwards Fraentzel washes out with warm distilled water, then for several days with warm salt water (one half per cent.), and afterwards, perhaps, with tinct. iodine (two to five per cent.), potass. permang. (one fifth per cent.), or acid. carbol. (two fifths per cent.). It would seem as if the cases of these two gentlemen might afford a chance for comparison of the two ways of operating antiseptically; but one possible source of error strikes us, and that is that distilled water is not aseptic, and there might be doubt also about a one per cent. spray of carbolic acid (the strength used by Fraentzel).

F. C. SHATTUCK, M. D., SECRETARY.

MYELITIS, ACUTE AND SUB-ACUTE, WITH A REPORT OF EIGHT CASES, BY S. G. WEBBER, M. D.

THE next case is also one in which there was a relapse, coming on after overexertion, perhaps with some exposure. These two cases teach us the necessity of cautioning patients who may be so fortunate as to recover from myelitis lest they should ignorantly overtax themselves. Of course it is scarcely necessary to say that the chances of recovery are much less after such a relapse.

CASE IV. John C., aged twenty-five, seen last October, was sent to me by Dr. Driver. Had worked hard carpentering, not exposed to wet nor cold. In May he took care of a man sick with erysipelas for about a week, running up and down stairs much. He then felt numbness in his legs from the hips down, which came on suddenly, he waking up in the morning with it, having been well the night before. No pricking sensation, no pain; his feet felt as if he had on "an awful thick pair of socks." No weakness, but it tired him to walk. These symptoms lasted about six weeks,

¹ Concluded from page 159.

gradually disappearing. After this he walked a great deal, peddling; he then opened a restaurant, and in two or three weeks the old symptoms returned, but not quite so bad. No pain. He had to use his eyes in walking. There was a loss of sensation in legs and absence of tendon reflex. The result in this case I have not yet learned.

In the next two cases syphilis was undoubtedly an active agent in causing the disease, at least in predisposing to it. In the first of these two the cord alone seems to have been affected; in the second there is sufficient reason to believe that the membranes were also affected. Time enough has not yet elapsed to settle the question of recovery, but both patients have improved. Both of these cases progressed rather slowly. As a general rule, syphilis of the cord is a very serious, even fatal affection, much more so than cerebral syphilis.

CASE V. Mr. A. was seen in consultation with Dr. Belt. There was a history of syphilis. He did not have a very hard position, but was necessarily up at night, and sometimes exposed to inclement weather. One night in August he was thoroughly wet by the rain, and left his clothes to dry on him. After this wetting he had a pain in his right side, running round to the umbilicus. About September 1st he had a tickling sensation in both great toes. In a week or two the numbness extended up the leg to the knee, and then slowly as high as the waist, advancing most rapidly on the right. He continued to keep about until the last of October. About two weeks previously, however, he suffered loss of power in his legs, and they occasionally gave out under him. One week before he was seen he took to his bed, not able to move the right leg, but he could move the left leg. Reflex action on tickling the soles of the feet was very marked in the right leg, less so in the left. Tendon reflex was exaggerated in the right leg. There was decided loss of sensation in both legs, less decided loss over abdomen. A line just above the umbilicus defined the limit of anæsthesia, passing around on the right level, but on the left running down diagonally towards the groin. Irritation of the skin in testing sensation caused, not the so called *tâche cérébrale*, but a general vaso-motor paralysis, the whole abdomen becoming bright red after the examination. Except as mentioned, in August there was no pain anywhere; there had been some pricking sensation, as if the parts were asleep. The bowels were obstinately constipated, and there was inability to retain the urine after a desire was felt to pass it. He had been taking iodide of potassium, and this drug was given in yet larger doses; oleate of mercury inunction was used and hot-water bags were applied to the back. He has slowly gained since.

CASE VI. J. E. T., age thirty-five, entered the City Hospital November 12, 1879. He had had chancre three times, the last time in 1864. In 1866 he had sore throat, but no other symptoms. He had spinal meningitis in January, 1878, and was confined to bed four weeks; his legs and hands were drawn up. Eight months before entrance, during coitus in an almost upright posture, he noticed trembling of the left leg. Within forty-eight hours the left leg became heavy and the foot numb; this feeling increased daily, extending upward. Five weeks later these sensations had reached the left thigh, and the right leg began to be affected similarly. There had been no tingling in his

feet and no pain; since the legs gave out he has had a sense of constriction about his waist and ankles. There was difficulty of micturition, and the use of a catheter had been found necessary.

During the three months before admission there had been spasmodic contractions of the legs, more marked in the evening and during sleep. At one time he partially regained the use of the right leg; then had a feverish attack in which he was delirious, since which he has lost ground.

At the time of entrance he was able to draw up his right leg, but not the left; could turn over in bed, but was unable to stand; tendon reflex was greatly exaggerated; there was diminution of sensation in the leg and lower part of abdomen; there was a burning sensation in the calf and the popliteal space; when the legs were spasmodically contracted there was a sharp, severe pain in the small of the back and in the abdomen. Temperature normal.

At first he was given fluid extract of ergot, iodide of potassium, and had dry cups to his back. After five days the ergot was omitted, and the iodide of potassium was increased gradually till he took forty-five grains three times a day. On December 8th he could manage his legs better; there was less spasm; he controlled his water; there was more sensation in the legs; and the sense of constriction was less marked.

In this case there were spasm and pain in the back, to lead to a suspicion that the membranes were somewhat affected. There was less decided loss of sensation than is usually seen when the central gray substance is the seat of the disease. There was probably an implication of the membrane, though undoubtedly the cord was chiefly affected.

In the next two cases there has been almost, if not quite, complete recovery. It may be a question as to whether there was inflammation or merely congestion. I cannot decide that with certainty. In Case VIII, probably there was congestion, or only the very initial stages of inflammation.

CASE VII. Mr. H. F. B. was seen with Dr. Wheeler, of Chelsea, July 31, 1877. He was conductor on a passenger train; had never been in an accident; had been on the railroad eleven years; for about eight years he ran eighty miles a day, but lately every four weeks he had lighter work, only sixty miles a day. Towards the latter part of June, on a public occasion, he stood up in a crowd for two hours, part of the time on tip-toe. Soon after that he had severe pain in his shoulders when putting his shoes on; also pain in the back and hands. The night of July 3d he sat in a draught, but moved out of it as soon as he felt it. During the first week of his illness he tried to work, but was obliged soon to give it up. He had then numbness and pricking sensations in both hands and feet; there was no pain excepting on motion; he was able to walk, and felt the floor with his feet; but towards the latter part of the first week his legs began to be weak, especially when going up-stair. These symptoms increased in severity till the end of the second week, when he could not feel the stairs, and had to look at the steps when going up to see whether his feet touched them. When the bowels moved he did not feel the motion, and the passage of the urine was not always felt; there was no incontinence. The numbness in the ends of his fingers caused him trouble in buttoning his clothes; he felt as if a string were tied round toes and fingers. There was no spasmodic action, excepting tremor

of the arm when going up-stairs. He walked and stood very unsteadily with his eyes shut; much better with them open. Reflex action still remained, not exaggerated. The æthesiometer showed no difference in sensation between the two hands; the feet were not tested. He improved under treatment, and I subsequently heard of him as recovered.

CASE VIII. E. G., age twenty-four, was admitted to the City Hospital October 10, 1879. He had used liquor, but not usually to excess. About a year before he had chancre, followed by rash, sore throat, and falling out of hair. For a week before his attack he had been more or less drunk, lying out-doors at night. Three days before admission he found he could not pass his water; there was also pain in the abdomen, but none in his back, and no vomiting. For three days there had been spasmodic twitching of the legs when he was falling asleep; there was a "sleepy," prickling sensation in his legs and arms when lying still and when walking, but no pain excepting about the bladder. He stood and walked fairly well even with his eyes shut; but when walking the right leg was put down harder than the left, with a slight stamp. There was considerable tremor of the hands. Sensation was diminished in the right as compared with the left leg. Tendon reflex was much exaggerated, especially on the right; the foot, after a blow on the ligamentum patellæ, being jerked up twice, and after the second jerk being held up for a few seconds, then falling slowly to its normal position. Even a slight tap was sufficient to excite the reflex action. The urine contained albumen, blood, and pus.

He was given a hot-air sweat, then fluid extract of ergot, one drachm three times a day, and was confined to bed. October 14th, all the unpleasant symptoms had disappeared, and he insisted on going home.

REMARKS.

In these cases, as in many others, there had been one or more of three ætiological conditions present, either syphilis, wet and cold, or overwork. In the syphilitic cases the other causes were present as well. To be sure many other patients have overworked themselves, and many who are not patients have been exposed to wet and cold. But in these cases and in others which I have not reported, the first symptom of the disease appeared in intimate connection with the exposure, and the parts first affected being those most exposed it is almost necessary for us to refer the origin of the disease to such exposure or overexertion. Thus when the feet were wet and cold the legs were first affected, as in Cases I. and III.; also after unusual exertion, in Case IV.

In Case II. the wet and cold were applied to the hands, and there was undue labor of the hands as well as of the legs. The following night the first symptom appeared in the thumb of the left hand, and it was only a week before the right hand was affected, three or four months before the feet were involved. Case VII. stood two hours, part of the time on tip-toe, and later in a draught. The first symptom appeared in the hands and feet. Case V. was exposed by having his clothes wet; then there was pain in the abdomen, and later symptoms in his feet. Case VI. is rather more complicated. Syphilis, coitus in the upright posture, an irregular life, various excesses and exposures, concurred in causing the disease. The attack began, after unusual exertion, in the legs. Case VIII. lay on the

ground all night in October; the first trouble he noticed was with the urine and legs.

In all the above cases, numbness or some other abnormal sensation was the first, or one of the first, symptoms noticed. This numbness is described differently by different patients, but seems to be a combination of prickling and anesthesia, with perverted sensation such as is felt when a limb is recovering from having been "asleep." This peculiar sensation may be so strong as to be extremely painful. Sometimes there is a feeling as if the leg was in hot water, or as if hot water were being poured over portions of it. Pain has been a comparatively rare symptom in those cases of myelitis which I have seen. In the case of one patient, aged sixty-two, who had been frequently exposed to cold and wet, and had worked very hard, there was acute, severe pain in the back. This pain ceased about the time that the numbness and weakness began in the legs. When pain is a marked symptom either the disease is situated near the periphery of the cord so as to implicate the pia mater, or the fibres of the posterior roots pass through the affected portion of the cord, or swelling causes pressure upon the membranes.

The motor symptoms, such as weakness, and inability to walk, may appear sooner than in the cases reported; generally a slight degree of motor disturbance or spasm will be found with the earlier signs. Contraction is a late symptom, and necessitates the integrity of the cells of anterior cornua and the anterior nerve roots at the level whence the nerves arise supplying the affected muscles. The contraction may be most marked during sleep. It is no unusual event to have a patient's sleep disturbed by the violent spasm in the limbs. When this severe it is the more probable that the meninges are affected.

In much the larger proportion of the cases which have come under my observation the sensory tracts were primarily affected. Considering that cold and wet, with exhaustion from overfatigue, play so important a part in ætiology, it is in harmony therewith that this tract should be first affected; the reflex vaso-motor and trophic influence, it would be supposed, would be first felt in the sensory tract.

In three cases the tendon reflex was exaggerated, sometimes very much so. In two it was absent. Other patients, who were seen before this symptom was brought into notice, showed an increase of reflex action.

I cannot now go into the pathological anatomy at any length. Other cases, which have had the same symptoms as those reported, showed at the autopsies the changes of myelitis, not always softening so as to be diffident, but parenchymatous inflammation of the nervous structures of the cord, either of the white or gray substance, or of both. Two of the cases reported showed that change.

As to treatment, the first essential is rest,—absolute rest in bed. A patient who feels perfectly well excepting a little numbness in his hands or feet or both, and a slight weakness in his legs in walking, scarcely noticeable; who has no pain, no discomfort; whose head is perfectly clear, and appetite remarkably good; who has no feverishness, can scarcely be made to understand that absolute rest is all important for recovery. This rest should be prolonged even after the immediate symptoms have disappeared. It is not safe to allow a patient to get up and be about too soon. All doctors, even, do not realize the importance of keeping

patients with myelitis in bed awhile after the symptoms have disappeared.

For active treatment ergot is the best drug to use, but of course be sure it is a good preparation. Counter-irritation in some form to the back is valuable, and dry cupping is one of the best methods. Other methods, such as cauteries, iodine, or blisters, also prove useful. Iodide of potassium is certainly indicated if there has been syphilis. In Case VIII., as the kidneys were evidently disturbed, a sweat was given to call the skin into activity and relieve the renal vessels. It is not unlikely that this may have been of benefit to the spinal cord as well. It might be worth while in a recent case to test the value of a sweating.

That a relapse is possible is shown by two of the cases reported, both of which essentially recovered, but in consequence of overexertion were again attacked. As might be expected, the second attack occurred after rather less exertion and exposure than before the primary attack.

The results in these cases show that myelitis, when treatment is commenced early, is not necessarily fatal. They do not show the true proportion of recoveries, for I have selected the cases with regard to aetiology and symptoms rather than recoveries. A large number of other cases which I have had under my care, or which I have seen, either have died or have been lost sight of. The prognosis is decidedly unfavorable as a rule; the recoveries are exceptional. If, however, the disease is recognized early the chances are much more favorable. A partial recovery is more likely to occur than a perfect one. A section of the spinal cord is permanently injured beyond all possibility of restoration; the disease does not advance, but the function of a portion of the cord being interfered with, the symptoms in the parts below the point affected persist; there is no possibility of perfect restoration. It is not often that the whole diameter of the cord is so seriously affected; more frequently, when there is partial recovery only, a small portion of one column or cornu is destroyed, and there is a proportionate restoration of function below.

DISCUSSION.

Dr. ELLIS expressed himself as much interested by the paper, and asked the reader how early the disease might be detected. A patient presents himself with slight numbness, but without any motor disturbance. Are we to suspect myelitis and confine him to bed? — Dr. WEBBER replied in the negative; but if there be numbness and pricking sensations, slight motor disturbances shown most perhaps in a peculiar gait, which the physician sees, but which may have escaped the notice of the patient, exaggerated tendon reflex, or any affection of the bladder, we are on the safe side in enjoining absolute rest. — Dr. ELLIS thought that there was often a good deal of difficulty in drawing the line between these cases and many others which one saw of numbness which comes and goes, lasts perhaps for years, but finally ends in recovery. — Dr. WEBBER said that he had seen these symptoms often, chiefly in elderly people, more often unilateral than bilateral, and hence hemiplegic rather than paraplegic. Under these circumstances they are due to poor circulation in the brain, perhaps from rigid arteries, or are purely reflex phenomena. But, having seen apoplexy follow these symptoms in two instances, he thought it well to be on the watch in such cases. — Dr. ELLIS said that he

had also seen this kind of perverted sensation in early and middle life and in women, and asked Dr. WEBBER whether he would agree to the statement that unless there be disturbance of motion as well as of sensation we need not fear myelitis. — Dr. WEBBER considered this a fair statement, and added that the personal peculiarities of the patient and the way in which he spoke of his symptoms afforded some help in diagnosis. — Dr. J. J. PUTNAM said that he had lately seen at least two men who had complained of numbness in the legs and fatigue on walking. After watching them for some time he came to the conclusion that their troubles were due to varicose veins. He then asked Dr. WEBBER on what grounds he had based his diagnosis of spinal congestion in some of the cases reported. Dr. PUTNAM could not see that a group of symptoms characteristic of congestion of the cord can at present be recognized, though there is no presumptive evidence against the possibility of such a condition. On the other hand, there is no proof that symptoms such as the reader described may not be due to actual inflammation which ceases at an early stage, and there is analogical support for this view. It is quite different in the case of the brain, where there is a pretty well marked group of symptoms which are distinctive and do not lead to inflammation, and which there is reason to attribute to congestion. In the case of the cord, furthermore, it is doubtful if it is fair to say that congestion is the first stage of myelitis. — Dr. ELLIS also criticised the use of the term congestion, and said that the symptoms may be due to anemia. A modification of nutrition is all that is needed. — Dr. WEBBER replied that he was perfectly prepared to admit that we have no absolute knowledge of congestion of the cord. But the inference does not seem unreasonable in view of the facts that congestion is the common precursor of inflammation, that similar cases beginning with the same symptoms end in inflammation found on post-mortem examination, and that slight cases run imperceptibly into the severer ones. — In illustration of the excessively rapid course which the disease may take, Dr. PUTNAM spoke of a case which had been under his charge. A woman was somewhat indisposed one day, having been apparently perfectly well before that, and on rising the next morning and walking about the room she had a peculiar feeling of suffocation. She lay down upon the bed, soon after vomited, and was then paralyzed from the neck downward. Dr. PUTNAM supposed the cause to be hemorrhage, but Dr. Seguin, of New York, to whom he mentioned the case, told him that he had seen a very similar case in which the autopsy revealed acute softening. In connection with the point of first appearance of the disease, he mentioned a case he saw in Boston. The patient had sat in a cold and wet place, and the first symptoms were confined to the rectum. He was told by two railway employees this summer that riding long distances produced a desire to urinate frequently, and a German railway physician states that railway employees are more liable than other men to diseases of the spinal cord. — Dr. FISHER being called upon said that his experience with myelitis was limited, but with cases such as those alluded to by Dr. Ellis very large. In cases of neurasthenia and anemia, numbness and pricking, often unilateral, are quite common, and recover under tonic treatment. They are generally due to changes in the circulation. The pathological lesion of cases of myelitis which end in recovery may be slight inflammation. We know

that the inflammation of general paralysis is often very slight. He then asked Dr. Webber what value he attached to tendon reflex. — DR. WEBBER replied that the phenomenon is one to which attention has been called so recently that he did not feel prepared to give a definite answer to the question. It is generally, but not invariably, absent in locomotor ataxia.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

FEBRUARY 9, 1880. DR. JAMES C. WHITE, permanent chairman, presided.

RAPID PULSE AND HIGH TEMPERATURE AS SYMPTOMS OF PUERPERAL INFLAMMATION.

DR. FRANCIS MINOT read the following paper: —

The state of the pulse and that of the temperature are generally reckoned to be pretty sure indications of the general condition of a woman after delivery. So long as they continue normal, or but moderately raised above the healthy standard, the physician feels free from anxiety; on the contrary, a rapid pulse or a high temperature always gives rise to apprehension lest it be the forerunner of some local inflammatory process or grave general disease.

But I have met with several instances in which a rapid pulse continuing many days after delivery gave rise to much anxiety, and yet no inflammation or other unfavorable condition followed. In a few cases high temperature was associated with rapid pulse, and the condition closely resembled peritonitis or septicæmia; but I am satisfied that in these cases the disease was purely functional, and dependent on some nervous condition, either of excitement or exhaustion. I will first relate three cases of rapid pulse in the puerperal condition. They occurred several years ago, and no temperature was recorded.

CASE I. In February, 1863, I attended a lady in her first confinement who was of a marked nervous temperament, though a woman of much self-control. She was the second wife of her husband, and the fact that the first wife had died in childbirth caused her to feel a certain amount of apprehension lest she might share the fate of her predecessor. The labor was in all respects natural, but the patient was unable to make water spontaneously for several days afterwards, being wholly dependent on the catheter. During that time, also, she was somewhat excitable and nervous, but free from hysterical symptoms. The most striking symptom she exhibited, however, was great rapidity of the pulse, which remained at about 116 to 120 in the minute for nearly a week, and then slowly subsided to 80. There was no chill, no heat of skin, no tenderness of the abdomen, or other sign of inflammation. I felt a good deal of anxiety about the safety of the patient, and watched for the first symptom of local trouble, but as none appeared I concluded that the rapidity of the pulse was owing to mental anxiety. She made an excellent recovery.

CASE II. In August, 1864, I took care of a lady about twenty-two years old, who was delivered of her first child with forceps, on account of inefficient pains. She belonged to a family of nervous temperament, though she herself was not excitable. During the first

half of her pregnancy she had suffered from excessive nausea and vomiting. Her convalescence after delivery was in all respects satisfactory, except that the pulse was at the rate of 120 a minute for several days. There were no other symptoms of inflammation. It would seem as if the family temperament, ordinarily latent in her, showed itself in the increased action of the heart.

CASE III. The same month another patient, also primipara, was confined. She was blonde, and had a strongly marked nervous temperament, as also had other members of her family. For years she had been troubled with irritability of the bladder, and had also been for a long time under treatment for supposed spinal disease, but she was in good health at the time of her confinement. The labor was natural, but the catheter had to be used for about a week, and the pulse ranged from 92 to 120 for a fortnight. There were no other symptoms of inflammation, and she did well.

CASE IV. In the next case both the pulse and the temperature rose suddenly, a few days after delivery, and the patient was apparently in great danger. The symptoms were supposed to indicate peritonitis, and the recovery was attributed to the treatment employed, especially injections of a solution of carbolic acid into the uterus; but after carefully considering the circumstances of the case, I am inclined to believe that there was no inflammatory disease, and that the patient might have recovered without any local treatment. She was under my care for more than nine weeks, and I will only give a brief outline of the case. On the fourth day after delivery, her condition having been, so far, perfectly satisfactory, she was seized in the evening with severe pain in the lower part of the abdomen. There was no rigor. At half past three o'clock, the next morning, she had a temperature of 105°, and a pulse of 132. The respirations were 36 in a minute; there was no pallor, no tympanites, no vomiting. The abdomen was soft, and tender in the supra-pubic region. The legs were not drawn up; there was a free bloody uterine discharge; the urine contained a considerable amount of albumen. (Intrauterine carbolic injection; six grains of quinine, three times daily; turpentine externally.) Evening temperature, 103.5° F.

Sixth day. Morning temperature, 104.8° F.; pulse, 120. Evening temperature, 103° F.; pulse, 108. (Carbolic injections.)

Seventh day. Morning temperature, 101.3° F.; pulse, 96. Evening temperature, 102.8° F.; pulse, 100. There were six loose dejections during the night. Abdomen flat, and hardly tender. The patient was more comfortable. (No injection.)

Eighth day. Morning temperature, 102.2° F.; pulse, 108. At noon, temperature, 103.4° F.; pulse, 108. At ten p. m., temperature, 101.3° F.; pulse, 104. Delirium during the day, which increased towards night, the patient trying to get out of bed. (Carbolic injection at ten p. m.; chloral hydrate and bromide of potassium.)

Ninth day. Morning temperature, 100.2° F.; pulse, 100. Evening temperature, 101° F.; pulse, 112. Much delirium; coldness of the extremities; aspect, hystero-manical. (No further intrauterine injections were given throughout the case.)

Tenth day. Morning temperature, 99.7° F.; pulse, 92. Evening temperature, 105° F.; pulse, 104.

Eleventh day. Morning temperature, 99.8° F.;

pulse, 104. Evening temperature, 102.8° F.; pulse 108. More comfortable; rational; the milk has disappeared from the breasts.

From this time there was gradual improvement, the evening temperature being two or three degrees above normal, till the seventeenth day, when there was some pain and tenderness over the left ramus of the pubes, with increase of pulse and temperature, the latter rising to 103.4° F. The symptoms slowly subsided, and on the twenty-second day the patient seemed convalescent; but a moderate attack of phlegmasia dolens set in on the thirty-ninth day, which lasted two weeks, the whole duration of the case being about sixty days. The albumen disappeared from the urine, and the patient recovered completely.

It will be noticed that although there was a subsidence of the temperature after each intrauterine injection, yet, on the other hand, the temperature also fell when none had been given. Thus, on the evening of the ninth day it was 104° F.; the symptoms were threatening, and yet the next morning it was 99.7° F. It rose to 103° F. the same evening, but fell again, the following morning, to 99.8° F. On the whole, considering the absence of chill, of vomiting, and of much abdominal tenderness, the continuance of the lochia throughout the normal period, and the predominance of nervous symptoms, I am of opinion that there was no inflammatory condition of the uterus or peritoneum and no septicæmia at the bottom of the alarming array of symptoms which this patient exhibited.

CASE V. This patient was a primipara, of nervous temperament. She had always been well and strong. Her labor began with a pulse of 96, which rose to 120 in the course of a few hours. The presentation was natural, but the pains were slow and feeble, and delivery was finally effected by forceps, without any accident. For some days the pulse fluctuated between 116 and 128 in a minute, and the temperature varied from 102° F. to 103° F. There was nervous excitement, and on several occasions she had to be etherized when the catheter was passed, which was frequently necessary. There was plenty of milk, and she nursed her child. There was some complaint of pain in the abdomen, but no tenderness except a little about the fundus of the uterus; no chill; no vomiting; the lochia discharge was sufficient. The filtered urine contained some albumen.

On the ninth day after delivery her condition was very unsatisfactory. Morning temperature 103° F.; pulse 122. Nursing caused so much nervous excitement that the child was taken from her, and fed by the bottle. There was considerable tympanites, but no abdominal tenderness except over the womb; no appetite; no chill; no vomiting; the lochia were light colored, not offensive, and sufficiently abundant. (Carbolized vaginal injections had been regularly given, at least twice daily, since delivery, as also in the preceding case.) She lay upon her side, and had no difficulty in moving. At three p. m. the temperature was 104.6° F.; pulse 136. There was an ominous groan with each expiration. Dr. J. P. Reynolds, who saw the patient in consultation, agreed with me as to her alarming if not dangerous condition, and it was decided to employ intrauterine carbolized injections. One was given at seven p. m. Soon afterwards the temperature was 104.8° F.; pulse 132. A second injection was given later. On account of the extremely sensitive condition

of the patient it was very difficult to administer the injections, and I doubt if they were thoroughly given. She had a comfortable night, and the next morning the temperature was 100.8° F.; pulse 112. No further injections were given. In the evening the temperature rose to 104.3° F.; pulse 132. The next day (the eleventh after delivery), morning temperature 103.6° F.; pulse 132. Evening temperature 101.7° F.; pulse 110. On the twelfth day the figures were about the same. On the thirteenth day the temperature was nearly normal. After this it varied very much for several days, being in the neighborhood of 99° F. in the morning, 104.8° F. at six p. m., and 102.5° F. at nine p. m. On the nineteenth day it became normal, and remained so. The pulse corresponded with the temperature. The patient recovered perfectly.

The same remark applies to this patient as to the preceding one: that although there was a marked fall of the temperature and pulse after the employment of carbolized intrauterine injections, yet the same thing afterwards occurred when none had been given. The patients were alike in temperament, and both at times had a hystero-maniacal aspect, and I would add that both were much benefited by morphia, chloral hydrate, and bromide of potassium.

The lesson which I would draw from the study of the above observations is that a rapid pulse and high temperature in puerperal women do not necessarily indicate an inflammatory condition of the womb or peritoneum nor septicæmia. They may be caused by some condition of the nervous system not yet well understood, and unless unaccompanied by other symptoms, such as rigor, suppression of the lochia, vomiting, great tenderness, fixed dorsal decubitis, etc., do not call for active, or at least hazardous, treatment.

I have seen apparently favorable results from the employment of carbolized intrauterine injections in well-marked cases of puerperal inflammation, and I believe in their efficacy; but in view of numerous reported cases,¹ in which they have been followed by dangerous and even fatal results, they should always be avoided when not necessary, although doubtless much depends upon the skill with which they are administered.

DR. C. E. STEDMAN had not heard the beginning of Dr. Minot's paper, which was timely and important. There had been of late more trouble than usual with puerperal patients; and last summer the Lying-In and the New England hospitals had had to close their doors. Nothing like an epidemic had been observed in private practice, but high temperatures and pulse were uncomfortably common. One perplexing matter to decide was the separation of milk fever from the puerperal inflammations. Some philosophers deny that the former should have a place in our nomenclature; others that it is a mild form of septicæmia. But in milk fever the temperature seldom if ever runs higher than 102° F., and the disturbance subsides when the engorged breasts are relieved of their burden. It is not so common now as when nurses and mothers-in-law denied systematically to the patient cold water, light bedclothes, and fresh air.

Several cases like Dr. Minot's had given the speaker much worry, from their close resemblance to the real disease. One of the undoubted cases was the follow-

¹ Among others, by Küstner, Fritsch, and Herwegen, see *Die Irrigation des puerperalen Uterus*, Schmidt's Jahrbücher, 1879, No. 9, page 269.

ing, when the fever began before labor was completed: The patient was a primipara, about thirty years old; the os dilated slowly and painfully (it was before Dr. Stedman used chloral in such cases), the pulse rose, the patient looked and felt exhausted, and the case had to be finished by the long forceps applied through an undilated os. After delivery the febrile symptoms increased, and the patient died, conscious, of pelvic inflammation, in three or four days. In contrast to this, a primipara, aged about thirty, was safely confined. On the second day came a chill, followed by temperature of 106° F. and a riotous pulse, giving unbounded anxiety to physician and family. But the case cleared up in a day or two, and the temperature, etc., subsided, when the nurse was changed, with whom the patient—a spoiled, imperious, and nervous woman—had had a battle royal of words. One day, a medical neighbor, who was ill, desired Dr. Stedman to see a patient whom the former had delivered a day or two before, and who had sent for him again. Dr. Stedman found the woman with a full bladder and puerperal fever. Of course she had to be closely cared for, while the attending physician went into quarantine, as respected midwifery practice. The patient died in about a week. At this time, Dr. Stedman was engaged to attend a particular friend, and at one A. M.—one hour after the time of seclusion agreed on had passed—he was called to the lady, who had an easy labor of a third child. But three or four days after she developed symptoms much more urgent than those of the last patient, as regarded pain, pulse, and temperature, giving rise to horrible fears. The storm blew over in a day or two, and proved to be the result of mental worries to a nervous system several sizes too large for her delicate body.

Last month the speaker saw in consultation, out of town, a young primipara four days after an easy labor, with milk secreted and lochia somewhat scanty, chill, fast pulse, tenderness, and temperature of 105.5° F. She was far from being a nervous person, and was perfectly collected, though she was aware of the anxiety felt for her. Her face was pinched, hippocratic. She had been possibly exposed to the influence of diphtheria and erysipelas near her. Under hot, weak carbolicized intrauterine injections, the symptoms rapidly disappeared and she made a good recovery. Dr. Stedman mentioned another case, lately seen, where from the dull, sleepy, and listless appearance of the patient, the high temperature and pulse, with absence of milk and scanty lochia, a grave prognosis was made; she speedily recovered under weak, hot carbolicized intrauterine injections and free stimulus. Dr. Stedman relied greatly on the *facies* of the patient in this disease; those cases which present a dull and apathetic expression being of a dangerous character. It is often difficult to make a diagnosis, and the physician would be oftenest right who had previous acquaintance with the patient, and who did not place too much reliance on one or two symptoms only.

In conclusion Dr. Stedman remarked that in the treatment of typhoid fever he had found the pulse to be the guide for prognosis and treatment, while in the *puerperal* inflammations the temperature required the most watching. He had seen recovery follow a temperature of 107° F. in typhoid, where the pulse kept down, but in the metria such a temperature, without reference to the pulse, would demand the most active attention.

DR. A. D. SINCLAIR said that during a practice of

twenty years he had met with but two or three cases of puerperal disease, until this last year, when he had seen quite a number, and that there appears to be something in the atmosphere which has caused a prevalence of the disease lately, just as he had found in his practice that patches in the throat were more common than in former years. The Lying-In Hospital had to be closed for a time, and although it had been carefully fumigated and cleansed, high temperatures occurred more frequently than formerly, and the greatest vigilance was necessary to prevent more serious symptoms from breaking out; he thought, however, that the treatment by intrauterine injections of those cases which threatened to do badly had proved to be of great service. He had frequently met with cases such as Dr. Minot had mentioned, and had never seen any of them end fatally, so that a tympanic abdomen and high pulse, without other indications of puerperal disease, he did not consider to be dangerous symptoms. In regard to the term "milk fever," he for his part considered that there was such a thing, and that in certain cases it was a proper term to use.

DR. F. C. SHATTUCK spoke of cases of high temperature arising from nervous excitement, mentioning the case of a woman in Montreal, where the temperature went up to 117° F. He also quoted English authors as saying that in inflammatory affections a high temperature, say 107° F., is very dangerous, while in these nervous cases it is not of much importance.

DR. REYNOLDS said that he had lately heard Dr. Sims express the opinion that you may have considerable heightening of the pulse and temperature in nervous cases without any danger. As to the local treatment by intrauterine injections of solutions of carbolic acid, he would inquire of Dr. Sinclair whether any accidents had occurred in the eleven cases which had been treated in the Lying-In Hospital.

DR. SINCLAIR answered that no accidents had occurred, and that usually great amelioration of the symptoms had followed their use.

DR. STEDMAN remarked that with the fountain syringe the injections could be given without any danger.

DR. RICHARDSON agreed with Dr. Minot in regard to the first three cases, but he thought the histories of the last two showed unquestionably the presence of some localized inflammatory process. Until within a few years obstetricians were apt to enumerate a long list of diseases which might follow a delivery, such as metritis, peritonitis, cellulitis, ovaritis, etc. The tendency of the present day is too much to the other extreme, and to group all these diseases as only different forms of puerperal septicæmia. This is a mistake. While as a rule these diseases may and do accompany puerperal septicæmia as a local lesion, there are cases in which, though rarely, they exist without giving rise to, or resulting from, any septic absorption. He agreed entirely with Dr. Stedman that in cases of puerperal septicæmia the temperature was of the greatest significance, and that the pulse was of no especial value except as a guide in the administration of stimulants. As regards the use of intra-uterine carbolic injections, he believed them to be of the utmost value, and had never seen the slightest injurious effect from their use. The fact, alluded to by Dr. Minot in the fourth case, that the lochia were not offensive cannot be considered an infallible sign that the interior of the

uterus is healthy. A patient died at the Boston Lying-In Hospital whose lochia were never offensive, and yet the autopsy showed that the whole of the lining membrane of the uterus was gangrenous and broken down. As to the influence of the mental condition on the pulse of the patient, he had lately seen a most exceptional case, in which a woman of marked nervous condition, who was subject to several hysterical attacks during the first five or six days following her delivery, had during that time a steady pulse ranging between 40 and 50, although her normal pulse was about 80.

Dr. REYNOLDS thought that accoucheurs ought to pay more attention to these intrauterine injections, and he doubted whether we were right in not using them where, for instance, we have a cellulitis. As yet we do not know enough about these processes, and perhaps ought to use injections more frequently for smaller troubles than those for which they were usually supposed to be indicated.

Dr. HODGES said that in surgery the thermometer was not considered a very important aid in connection with inflammations of the serous membranes, especially the peritoneum.

A few months ago a gentleman was thrown down by a horse, and bruised or trodden upon. During the night following the accident symptoms of peritonitis developed, and he died at the end of five days. At the autopsy eleven inches of the small intestine were found torn from the mesentery. The thermometer ranged from 97.4° F. to 99.8° F., with one exception, when, eighteen hours after the accident, it reached 101.5° F. The pulse steadily rose from 100 to 132.

A female, with malignant disease within the abdomen, accompanied by ascites, and seen in consultation with Dr. Wyman, of Cambridge, about the same time that the previous case occurred, also had peritonitis, as shown by chills, heat, pain, especially at the hypogastrium, tenderness, tympanites, rapid pulse, and the lymph in the fluid drawn off. The temperature on the second day was 100.2° F., on the fourth day 97.4° F., and on the ninth day 98.6° F. In a note written me at the time, in which Dr. Wyman speaks of low temperature in peritonitis, he says in regard to another serous membrane, the pleura, "I was asked to see a woman with chest symptoms, just a week ago. She was confined five weeks previously. I diagnosed empyema. Last Sunday two pints of pus were removed. The previous temperature was reported about 100°. The day after the puncture it was 97.2°, on the third day 97.2° (morning), 99.8° (evening), on the fifth day 99°. These cases correspond with others of which I have notes. They followed the rule that the thermometer gives us but little reliable information as to the severity of inflammations of serous membranes."

Dr. W. F. Whitney, who assisted me in the care of the injured gentleman first spoken of, was good enough at the time to look up authorities in regard to temperatures in peritonitis, and sent me the following memoranda, which I will read:—

"Loxain (Paris, 1877) gives eight cases of puerperal peritonitis, in all but two of which the temperature rose to 104°, and over, within twelve hours. In the latter it reached that point within forty-eight hours."

"Winckel says, 'The type of fever in peritonitis is sub-continual, as a rule. The rise of temperature is very quick after a few hours, showing a change of 1.8°

to 2.7°. The temperature varies from 102.2° to 105.8°, and the exacerbations are in the afternoon or evening. At times there are strong remissions to 100°."

"Kunze says the fever in acute diffuse peritonitis, which is almost always present from the beginning, is joined to a rapid elevation of temperature."

"Niemeyer says fever is one of the symptoms of acute diffuse peritonitis, and when this does not begin with the disease it occurs very early. The temperature rises to 105°, or more. Wunderlich, on the other hand, says that in inflammations of the great serous cavities there is absence of any typical character. They may run their course without any fever, or may have a high one. Of peritonitis, he says subnormal temperatures (96.8° to 97.7°) are especially common, and always highly suspicious. Death very often occurs with temperatures below the normal, which may either result from a fall shortly before death, or may have lasted some time already, or have alternated with normal and elevated temperatures. Peritonitis, especially when puerperal, may develop a very high temperature, and this is a bad prognostic."

"Other authorities in England also confirm the statement that uncomplicated inflammations of the serous cavities are accompanied by slight fever, often not over 100°."

These somewhat conflicting statements would certainly seem to indicate that there is a degree of ambiguity in the thermometry of inflamed serous surfaces, which requires something more than mimetic cause to explain the conflicting evidence of a rapid pulse and a low temperature.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

T. M. ROTCH, M. D., SECRETARY.

JANUARY 31 and FEBRUARY 14, 1880. Dr. CALVIN ELLIS, the president, in the chair. On motion of Dr. F. A. HARRIS it was voted that the society should meet once a fortnight.

LAW TO REGULATE THE PRACTICE OF MEDICINE.

Dr. E. W. CUSHING, in reporting the measures which have been taken by the committee of the American Social Science Association to perfect its draft of a proposed law to regulate the practice of medicine for the protection of the community, said that as at and after the reading of the first draft of such a law at a meeting of the association, in November, some opposition was manifested, it was deemed proper to test the feeling of the profession in the State. After consultation with gentlemen eminent in the medical and legal professions, a printed copy of the amended draft of a law was sent to seventy-five physicians, selected as representative men, in various parts of the State, outside of Boston, together with a circular asking for suggestions and the use of their names as approving the general purpose and principal features of the proposed law. Of these some few failed to reply, while many wrote at length, showing the pressing need of such a law, and offering valuable suggestions and the use of their names. Only two wrote refusing to approve. Encouraged by this, the committee had printed eleven successive editions of the draft, each embodying some new and valuable suggestion, obtained by a wide correspondence with physicians of this State, and with

the boards of examination in Illinois, Texas, New Hampshire, and the British Provinces, where, as well as in Vermont and Alabama, such laws are in successful operation. The leaders of the other two state medical societies were consulted, and by correspondence it was found that the proposed law would meet with their approval and that of their fellow members. The reason for this rather unexpected unanimity may be found in the manner in which the matter was presented by the eminent non-medical gentlemen having charge of this movement. It was very evident from the first that this is no attempt of physicians to get themselves protected, or of one society to oppress the others, but that it is a movement, supported by the thoughtful part of the community, against the disgraceful state of things in the commonwealth, which was so prominently brought to public notice by the so-called "trunk tragedy." The presidents of the Associated Charities and of the Boston Provident Association are on the committee which has brought the matter before the legislature, in conformity with the suggestion in the governor's message. Many of the first citizens of Boston headed a petition to the General Court, asking for such legislation, which was printed with their names annexed, and circulated widely in the State, everywhere receiving the signatures of leading citizens. Encouragement by word and letter has been offered to the committee from all quarters in the most gratifying manner. The clergy have shown a deep interest in the subject, as being a matter of public morality, and in fact there seems to be a general consensus of the competent that something ought to be done, and that the manner and means proposed are suitable and efficient. The committee was fortunate in securing the assistance of an eminent member of the bar, formerly on the judiciary committee of the legislature, who has condensed its draft, and put it into legal form.

In regard to the attitude of the profession in this matter, it is sufficient to say that its members approve of this movement, but do not sign petitions, being, on the one hand, unwilling to ask for what many would erroneously consider a bill to protect their pecuniary interests; and, on the other hand, being unwilling to obstruct a movement eminently useful and proper, merely from questions of personal taste and professional feelings, in the matter of serving on an examining board containing members of the other state societies; while it must always be remembered that the leaders of those societies, in consenting to support this law, which they could easily defeat, and in consenting to form a small minority of such a board, have trusted to the honor of the stronger society never to use its majority for the purpose of discriminating unfairly against their schools or candidates for licenses.

The provisions of the proposed law were then explained, and it was stated that the condensed draft contains all the important points of the former and longer one, which was the result of so much careful comparison of existing American laws, so many valuable suggestions, and such wide correspondence.

DR. D. W. CHEEVER offered some objections to the proposed petition to the legislature, as follows:—

MR. PRESIDENT,—I avail myself of your permission to state my views on the proposed petition to the legislature for a law to suppress quackery in this State.

But one side of the question has been presented. The results of the legislation asked for seem to some

members of our profession disastrous to the true interests of the members of the Massachusetts Medical Society.

It is proposed to have a state board of medical censors, consisting of five Fellows of the Massachusetts Medical Society, two Fellows of the Homœopathic Medical Society, one Fellow of the Eclectic Medical Society, and also one dentist, appointed by the governor and council, to examine and license to practice all future physicians, of all classes, in this State; and that those failing in such examination, or not seeking a license, shall be prosecuted as quacks, and forced to quit practicing in Massachusetts.

The object sought for is worthy and desirable could it be made practicable in operation, and could it be left in the hands of the Fellows of the Massachusetts Medical Society. It is not proposed so to leave it. But an offer is thus made by the fourteen hundred members of the Massachusetts Medical Society to the one hundred and seventy-five members of the Homœopathic Society, and the one hundred members of the Eclectic Society, to join hands, occupy one common position before the public, and have equal standing and equal rights (*pro rata* to their numbers) in deciding who are and who are not irregular practitioners of medicine.

(1.) This constitutes the first objection: We ask those whom we have denounced and expelled from our society as irregulars to join us and judge *who are irregulars*. We extend the ægis of a legal license to those with whom we have recently refused to associate. It would be much more logical to invite them back again to be members of the Massachusetts Medical Society.

(2.) The second objection is that the power of appointment and of judging who are fit and who are unfit to hold the supreme office of state censors is put in the hands of the governor and council, and the selection is not left in the hands of the sole party competent to judge, the medical profession itself. To what results this might lead in ten or twenty years we will leave those familiar with politics to decide.

(3.) The third objection is that such a law as is proposed will be as impossible of execution as a liquor law. The most stringent measures under despotic governments, as in France, have failed to suppress quackery. Will there always be found an American jury with not one spiritualist or quack medicine manufacturer or vendor upon it?

DR. CORNELL spoke of the inconsistency of the proposed law, so far as members of the Massachusetts Medical Society were concerned.

DR. CHADWICK, as an advocate of the proposed act, said: I accept Dr. Cheever's definition of its aim and scope. (1.) Without pretending to know the motives which led to the expulsion of the homœopaths from the society, a good and sufficient reason exists in the fact that their practice is entirely based upon theories which we believe to be utterly false. If the conjoint board of examiners were to consider such questions, I should oppose this act. But inasmuch as the examination of candidates is expressly restricted to those branches of medical science which are accepted by and indispensable to all who practice medicine under whatever system or belief, I see no inconsistency in members of the Massachusetts Medical Society serving upon this board. And as it will not be known to the board what system of medical prac-

tice a candidate intends to adopt until after the examination is concluded and its result recorded, I do not think our members can be said to "license irregular practitioners" in any objectionable sense of the term.

(2.) While the medical appointments made by the governor and council may not have invariably been the very best, yet when we look at the character of the men occupying positions as medical examiners, and upon our state and city boards of health, and at the efficiency with which their responsible duties are performed, I see no reasonable ground for doubting that suitable men will be appointed upon the proposed board.

(3.) As to the impossibility of carrying out the act, if passed, I can only say that similar, though much less efficient, laws have been carried out in six or eight other States of the Union, and have conduced greatly to the welfare of the communities and to the elevation of the profession, as is shown unequivocally in the published reports of the several boards. I will not admit that the physicians of this State are less capable of performing such duties than those of other States.

Dr. GAY said that in other States he found that laws of this kind had resulted in driving away "medical tramps," but had not affected resident irregular practitioners; that it was his opinion that such a law would make quackery respectable. — Dr. ORDWAY remarked that a theoretical bill of this kind could not be passed through the legislature. — Dr. BECKINGHAM said that there was nothing in this law to prevent the worst men from practicing; for these men are often the smartest, and will pass the examinations.

Dr. CUSHING spoke of the large number of physicians and others who had been consulted in arriving at the present form of the law; said that the committee in charge of it had been asked to get the views of the profession in the State, which is practically unanimous in approval of the present draft, and as this would come before the committee of the legislature for a hearing in three days, and was already in the hands of every member of the General Court, it was rather late for any alterations. He drew attention to the fact that the letters of Dr. Gay showed that the law was effectual in protecting the people of New Hampshire from tramps and charlatans, although it did not reach "irregulars," among whom the correspondents of Dr. Gay probably included homeopaths and eclectics, against whom this law is not aimed, as the State has no right to interfere with any one's opinions concerning therapeutics, but can and should inquire into the moral character and education of all who attempt so serious a matter as the practice of medicine. He read a letter from the president of the Board of Medical Examination of Quebec, who said, "I have given the subject my most careful attention and consideration, and regard the whole scheme as a very happy one, and likely to attain the desired result of protection of the community. . . . The Quebec law has been very effective, is well supported by the press, by public opinion and juries, is not difficult of execution, nor likely to fail." Dr. Cushing referred also to letters in his hand from the presidents of examining boards of New Hampshire, Illinois, and Texas, who all approved of this form of law, and had made valuable suggestions to those who had drawn it.

Dr. HUNT said that this proposed law was ridicu-

lous and unwise, and that it was contrary to all the philosophical reasoning of Adam Smith and Herbert Spencer.

Dr. WIGGLESWORTH responded that the Social Science Association had not inaugurated this reform as philosophers, but as public-spirited citizens.

As to the three original objections to the law, considered in inverse order, the third says practically, "Though the law is good, we fear it may not succeed; therefore we oppose it." Such reasoning is not only faint-hearted, but illogical. If the law is good, let us put our shoulders to the wheel, and at least do our duty by aiding it as far as we can, and thus satisfy our consciences. If it fails of success because the community is not as yet educated up to it, it will at least not fail as a means of education. We do not expect to attain perfection at one bound; but unless a first step is taken no progress will ever be made.

The second objection might be raised against all government appointments, and is a mere stricture upon republican institutions. We can judge of the future merely from the past, and surely every one is satisfied with the appointments to the state and city boards of health, to the hospitals, to the office of medical examiners, etc.

The first and practically the only objection is based solely upon feeling, rather than upon reason and philanthropy. A few of the elder members of the profession naturally grieve at the failure of their attempt to elevate the practice of medicine to a point beyond the comprehension of the average patient. All the more reason, then, for proceeding at present with more moderation, and for profiting by the assistance offered us against the common enemies, not of varying methods of practice, but of the community. This feeling, moreover, is confined to this city almost exclusively, while the law is a state measure. The state as a whole has been appealed to, and from every city and town and village come, not merely assenting, but most enthusiastically approving letters. Only two gentlemen wished to be excused from active exertion in behalf of the law. [Several letters were read, and a large bundle was shown.] And because this is a state measure, the exclusive management *cannot* be "left in the hands of the Fellows of the Massachusetts Medical Society." The State recognizes three societies, principally owing to the fact that the mistake, as a matter of policy, of the Massachusetts Medical Society enabled other societies to raise the cry of "Persecution!"

Finally, and most important of all, gentlemen carried away by their feelings forget that this is not a medical society matter. It was inaugurated by private citizens as a means of opposing the actual homicide, mutilation, and robbery of the ignorant and credulous lower classes. Poor victims, injured in health or person, and stripped of their means of support, are daily turned over by ignorant and criminal "quacks" to our hospitals to be supported at the public expense. Their families are thrown upon the community; meanwhile the "quack" is shielded from the consequences of his malpractice; and the money obtained by the latter is hardly spent for the welfare of the community. All that physicians are asked to do is to express their individual opinions upon a matter in which they have had exceptional experience.

Dr. WEBBER said, in speaking in favor of the law, that we here had an opportunity to protect the pub-

lic. It is well to make a beginning and to prepare an entering wedge for something better. The law will probably tend to diminish the ranks of the homeopaths. — DR. J. G. BLAKE wished, as a duty, to express a strong feeling in favor of the bill, which he thought of great importance to the community in guarding the public health. — DR. C. H. WILLIAMS said that no matter how carefully a bill may be drafted, it will not be successful, for the fault lies in the community itself. The people *will* employ quacks, and they do it with their eyes open, knowing that they are quacks. — DR. CHEEVER said that the Massachusetts Medical Society has a charter which cannot be taken away from it, and which grants the right to practice to its members, which cannot be taken away by any subsequent law. By the New Hampshire law each state or county society has its own board of examiners and licenses its own members. That plan is not open to the objections which exist in the law which we are now considering, and perhaps something of this kind might be advantageously carried out here.

DR. CHADWICK replied that, while the right to "license to practice" conferred upon all members of the Massachusetts Medical Society in its original charter secures that society against the concession of any similar right to any other set of men to the exclusion of its members, several prominent lawyers and legislators had given their unqualified opinion that the legislature had the full power to "regulate" the practice of medicine, and such would be considered the operation of this law. He thought it curious that Dr. Cheever should prefer the medical act of New Hampshire, when several of the members of the board in that State had expressed themselves as greatly preferring the provisions of our bill. Dr. Chadwick objected to the licensing of its members by each of the three societies, because three different standards of proficiency would thus be established, and because the day might come when one of these three societies might become so degraded as to admit to membership, and thereby to license to practice, with little or no examination. The temptation thus to increase its importance would be constantly before each society.

Recent Literature.

Transactions of the American Ophthalmological Society.
Fifteenth Annual Meeting. Newport. 1879.

The present volume of the *Transactions of the Ophthalmological Society* contains but little of general surgical interest. There are some exceptional cases reported and some very ordinary ones. As a rule the articles are not exhaustive; they rather suggest than instruct.

Dr. Henry D. Noyes furnishes an account of a plastic operation at the inner canthus, which he would not have referred to as "not described in the textbooks" if he had carefully consulted Szymanowski's *Handbuch der operativen Chirurgie* (page 225); this reference is of additional interest in this connection from the fact that Hasner's criticism concerning the effect of the transplantation of a portion of the orbicularis muscle is there noticed. Dr. Knapp's papers are of more special interest; two of them contain accounts of tumors of the optic nerve and a case of sarcoma of the choroid removed at an early stage, while

a third suggests a T-shaped opening of the capsule in hypermature cataracts, and the omission of the iridectomy in cataracts complicated with marked fluidity of the vitreous. In Dr. Derby's paper we notice twelve cases in which the left eye was more myopic or less hypermetropic than the right, and two cases in which the opposite condition prevailed; this marked divergence from the general law which is believed to obtain in these cases may emphasize the care needed in dealing with a limited quantity of medical statistics. The paper of Dr. Theobald upon the treatment of strictures of the nasal duct contains an account of the cure of five cases out of a total of twelve; this meagre result was, however, obtained by using probes four mm. in diameter. When we recall the fact that this is about the diameter of the bony duct, we may conclude that the twelve of the original twenty-four cases who did not continue treatment decided with a certain degree of wisdom; it is more than probable that the force implied in this method of treatment displaced a certain amount of careful study of the conditions of the lid, of the nature of the accompanying blenorrhœa, of the condition of the eye itself, and of other concomitants. Of the other papers of interest to the general practitioner we would mention that of Dr. Coggin upon Ischemia of the Retinal Vessels of both Eyes following Facial Erysipelas, and that of Dr. C. S. Bull upon Hyperostosis and Periostosis of the Bones of the Orbit. D. II.

The Mouth and Teeth. By J. W. WHITE, M. D., D. D. S., Editor of the Dental Cosmos. Philadelphia: Lindsay and Blakiston. 1879.

This is the seventh volume of the *American Health Primers*, and contains in a condensed form much valuable information. From the point of view of the dentist the teeth are perhaps more important to the general health than any other set of organs. Without them mastication and digestion are but imperfectly performed, and the whole organism suffers.

The information here given, though of the briefest, is such as no one should be without, and even the practitioner of general medicine might find some useful hints to aid him in the routine of his daily duties.

The first three chapters are introductory, and devoted to the Anatomy of the Teeth and the surrounding parts. Chapter IV. is on the Development of the Teeth, and states facts not generally appreciated even by the dentist, of the early appearance of the germs of the second sets, which have their corollaries on pages 79, 97, and *passim*, where reference is made to the necessity of care for the health of the mother during the whole period of gestation and nursing, for the sake of the child's teeth.

The chapters on the Temporary Teeth, Sixth Year Molars, Food, Constitutional Peculiarities, Irregularities, and Hygiene of the Mouth are especially valuable, and may be read with profit even by dentists.

Such a book is not supposed to do more than give hints, which the intelligent seeker for further knowledge can easily follow up, and should not be regarded as a complete treatise on its subject. Every parent who has young children to bring up should possess and study it. Its hints wisely followed will not lead to self-treatment, as do too many of the popular books of the day that treat of health, but to early and regular visits to a competent dentist and a careful following of his advice.

Medical and Surgical Journal.

THURSDAY, FEBRUARY 19, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, OSGOOD AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, OSGOOD AND COMPANY, BOSTON, MASS.

A PROPOSED ACT TO REGULATE THE PRACTICE OF MEDICINE IN MASSACHUSETTS.

THE attention of our readers is called to the draft of a proposed act to regulate the practice of medicine in Massachusetts, and to the report of a late meeting of the Suffolk District Society, at which this proposed act was discussed. These will be found in full in another part of our present issue. More than once of late we have had occasion to direct attention to the existence and more or less satisfactory operation of somewhat similar laws in other States and countries. The discussion of the subject was taken up by the health department of the Social Science Association, and the first draft of the proposed act originated in that body. The final draft, as about to be submitted to the committee of the legislature, is the result of consultation with men of standing in various walks of life, with a large number of physicians in all parts of this State, and with men concerned in the operation of similar laws elsewhere. The draft as now presented is drawn up, there is every reason to believe, in the interest of the State at-large.

Many criticisms, both general and special, easily suggest themselves. Most of these will be found elsewhere. Some of them would not be made, we think, and others would find an easy answer, if it were borne in mind that there are two interests to be considered, which it is hoped at some day, perhaps a distant day, to make one, namely, the interest of the public and the interest of the practitioner. The liberal man, whether physician or layman, should give each of these interests its due weight.

Should the proposed act become law, we do not see how the public at large can be injured. The governor and council might appoint inferior men to the board of censors, though the past leads us to hope and expect that fit men would be appointed: the censors may neglect to prosecute or fail to convict offenders, which seems to us a much more probable difficulty. Should, however, these fears be realized, in what respect would the public be worse off than at present, when any individual, male or female, however ignorant, may practice medicine on his fellow-beings with an impunity which it would be impossible to increase? On the other hand, it appears to us that there is sufficient reason to hope that the proposed act may be of immediate positive benefit to the community, and that, if it answered such moderate expectations at first, time and experience might show where its provisions could be improved and its operation made more effectual.

Neither do we see how the act, even if it failed to meet the hopes of its advocates, could work any injury to the intelligent and respectable practitioner; and if it meets the hopes of its supporters it will be of an equal service to him and to the public. The ignorant charlatan, whom it is hoped to reach, will not like the act, the believer in the inalienable right of the American citizen to do what he pleases with himself will not like it, and there are some members of the Massachusetts Medical Society who do not approve of it. These last are called upon to sacrifice a sentiment; we do not believe they sacrifice any principle. In return there is the possible attainment of real public benefits, and it is perhaps permissible to hope that a law of this kind may open the way to the gradual renunciation of dogmas, which even now, we take it, have no very strong hold upon the heads and hearts of their enunciators. We do not expect that an act of the legislature will reverse the law of gravity, or purge the commonwealth of all fools and knaves. Something may be done, however, if the community is ripe for it, as something is done to control the adulteration of food, the character of buildings, the standing and attainments of the legal profession.

The proposed act seems to us worth trying, and should it become law we hope the profession will give its cordial coöperation.

MEDICAL NOTES.

—We learn from the *Pacific Medical and Surgical Journal* that the supreme court of California has at last rendered its decision in the case of Dr. Frazer, sustaining the medical law as constitutional. The question is now settled definitively. The decision was unanimous, and is therefore irreversible for at least seven years, according to the new constitution.

—According to the *British Medical Journal*, a petition to two ladies is being signed in Edinburgh asking their consent to be nominated as managers of the Royal Infirmary at the January election by the court of contributors. The petition states that since nearly one half the patients are female, and the nursing staff entirely so, the petitioners think there should be some female managers.

—“We lately mentioned with regret,” says the *Medical Press and Circular*, “that our contemporary, *Guy's Hospital Gazette*, had been placed under the inquisitorial control of the treasurer of the hospital, and that in future nothing would be permitted to enter its pages without first undergoing supervision. Such a state of things is of course incompatible with honest journalism, and this week the humiliating announcement is made by the editors of that journal that, ‘under the circumstances, they will be unable any longer to continue its publication.’ That such an abuse of power should be possible in this age, that a layman should be allowed to gag the press in order to suppress opinions contrary to his narrow-minded bigotry, is simply astounding! While con-

gratulating the editors of the *Gazette* upon their determination, the question arises, "What will the staff do?"

—Schlaefke, in *Græfe's Archiv*, calls attention to the fact that when calomel is applied to the eye, if iodide of potash be simultaneously given internally, severe inflammation of the conjunctiva is liable to arise. He explains this result by stating that there occurs a formation of the iodate and iodide of mercury, which, in the presence of common salt or iodide of potassium, are soluble and act as caustics.

—Those of our readers who have seen and used Pond's sphygmograph have already been convinced of its utility. It is more manageable than Marey's instrument, which, by comparison, is clumsy. Moreover, the usefulness of the latter is impaired by the frequent difficulty of its adjustment. It must always be bound to the arm, and its lack of compactness renders it inconvenient as a bedside instrument. On the other hand, Pond's sphygmograph is so compact that it can be carried in the pocket. The patient has merely to place the wrist in a metallic rest to which the instrument is attached. It may, however, be used without the holder. Its delicate diaphragm has only to be held upon the radial artery as a stethoscope is applied to the chest. Consequently, in taking the pulse, the physician can use it with ease, and the pulse tracing of one visit may be compared with that taken at the next. Thus the progress of the disease may be followed more closely than would be possible if the finger alone be used in taking the pulse, for no finger is so finely educated as to be able to give the physician so accurately the varying qualities. Moreover, warning may sometimes be given earlier and with more certainty than by any other means, as in the cardiac paralysis which occurs in typhoid fever. It is of value in diagnosing and localizing aneurisms. It is so simple in construction as not easily to get out of order, and in every way is satisfactory for use in private practice. Our readers who are not familiar with this instrument will find a description and illustration of it in the *JOURNAL* for June 28, 1877.

—According to the Paris correspondent of the *Medical Press and Circular*, M. Richard, in a paper on the treatment of naso-pharyngeal polypus by the injection of chloride of zinc, read before the Surgical Society, cited the case of a lad who entered the hospital to be treated for epistaxis. A large naso-pharyngeal polypus was found compressing the velum palati and interfering with deglutition. Operation having failed, the tumor was injected with a few drops of a solution of chloride of zinc (proportions not mentioned). After a few days a large white slough was detached, and the injection was renewed. In three weeks the lad was dismissed, cured.

—In the annual report of the Massachusetts School for Idiotic and Feeble-Minded Youth Dr. Tarbell says:—

"During the past year I made a brief visit to the institutions for feeble-minded at Syracuse, N. Y., and Columbus, Ohio, Dr. H. B. Willbur in charge at Syracuse, and Dr. G. A. Doren at Columbus, and I cannot close this report without again calling your atten-

tion to the great need of more room for out-of-door work for our boys. Could you see the farm-work carried on by the boys at these two schools, you would be convinced, as I was, that no school can compare favorably with the best until it has land upon which to employ and educate its boys. At Columbus, a school of four hundred and seventy-five pupils, the boys, under the direction of one farmer and one gardener, raise all the fruit and vegetables used in the institution; keep the grounds in fine order; take care of a herd of twenty to thirty cows, ten to fifteen horses, and pigs innumerable,—in fact, do all the farm-work on an estate of about two hundred acres, and for an institution of five hundred to six hundred persons. At both institutions various trades and manufactures are taught, and carried on to a limited extent; but both superintendents were agreed—and were emphatic in their statements—that farm-work was not only the most profitable, but developed the slumbering faculties and senses of the boys more rapidly than any other method of education, and certainly rendered them more nearly self-supporting than any other occupation. During the coming year I hope to introduce into our shop some of the simpler trades or manufactures, not with any idea of profit, but simply to carry out in a more practical way the avowed object of our school."

—M. Georges Herbelin, a medical student at the Hôpital St. Eugénie, in Paris, according to an account given in the *British Medical Journal*, was buried on Tuesday last with well-deserved honors. The young man, whose courageous devotion to the sick had won the admiration of the hospital authorities, caught diphtheria while tending a little girl suffering from that terrible malady. Before dying, the brave student had the satisfaction of receiving the Cross of the Legion of Honor, which was taken to him on his death-bed, and which he clasped to his breast as he expired. M. Lepère, minister of the interior, M. Herold, prefect of the Seine, several municipal councilors, and a number of leading physicians and medical students attended the funeral. A detachment of infantry rendered him military honors. Several speeches by professors of the faculty were made over his grave. It is remarkable that the father of the deceased, who was a medical man, lost his life in the same way.

—The *British Medical Journal* states that M. Schwartz speaks in the *Archiv für Gynäkologie* of an extraordinary and shocking case, in which a midwife, by inconceivable violence, seems to have torn away during the act of labor what she described as "the rest of the after-birth," but which, when examined by the physician, proved to be the whole of the uterus. The ovaries and Fallopian tubes remained in the abdomen. The uterus is preserved at Halle. The woman recovered in fifteen days, and has since enjoyed good health. Venereal desires still existed, although less pronounced, and coitus was accompanied by less obvious sensations.

—One tenth of a grain of apomorphia introduced hypodermically, it is said, will relieve the orthopnea of asthma in a surprisingly short time.

— We find the following in the *Medical Press and Circular*:—

"A few days since there died at Herne Bay, whither he had retired from a busy London practice, at the ripe age of eighty-two, Mr. Thomas Hunt, a member of our profession, whose literary efforts a few years since attracted considerable attention from the facetious portion of the lay press. 'Hunt on the Skin' was too much for *Punch's* sense of the ridiculous to resist. "'Hunt on the Skin,'"—'it is too bad to be thus instructed publicly in newspaper advertisements: it would be shocking in cold weather: in hot—bah! it makes one feel creepish all over. Gentle reader, whenever you see this reminder in the literary announcements, "'Hunt on the Skin,'" take *Punch's* advice, and don't.' Hunt's little book was certainly illustrative of the familiar query, 'What's in a name?' By it the treatise—one not of the highest order of merit—sold extensively, and the author made a considerable practice."

PROVIDENCE.

—A circumstance illustrative of the so-called "liberality" of sentiment which prevails among a certain portion of the profession has recently occurred here. At a meeting of the Rhode Island Homœopathic Medical Society held in this city last week, a well-known member of the Rhode Island Medical Society was present, and responded to the following toast: The Rhode Island Medical Society,—distinguished for that broad culture which insures liberality. In the course of his remarks he predicted that the time would soon arrive when there would be no distinction between the two schools of medicine. He failed, however, to state the grounds upon which he based this prediction.

NEW YORK.

—It seems that the individual who died in the latter part of November last from eating a lemon meringue pie was not poisoned by verdigris from the copper vessel in which the meringue was prepared, as was at first supposed, but by an aniline dye introduced into it in some mysterious way that still remains unknown. The coroner's inquest has just been concluded, and this was the verdict of the jury, upon which there were six medical men. The deputy-coroner, Dr. D. B. Miller, testified that at the autopsy evidences were found of the presence of an irritant poison, and that death was due to gastro-enteritis. Dr. Hermann Endermann, an expert chemist, found present in the meringue that was left uneaten a quantity of dye of strong acid properties,—about three centigrammes to the ounce, or about one per cent. of the interior filling of the pie. The dye, by chemical tests, was proved to be aniline yellow, such as is used exclusively for dyeing wool; and its toxic character was demonstrated by experiments on dogs, which immediately after its administration exhibited symptoms of acid poisoning. There were no precedents to establish the extent of its injurious effects upon the human organism. Dr. George A. Prochazka, after explaining the tests that he had employed, testified that in both

the stomach and liver of the deceased (which were analyzed separately) he had found appreciable quantities of a yellow dye, the shade of which, as well as the manner of obtaining it, conclusively demonstrated its identity with that found by Dr. Endermann in the pie. No other metallic poisons could be detected, and the amount of the dye found in the stomach was greatly in excess of that in the liver. Dr. Alfred Purdy, who attended the man in his illness, described the symptoms present and the treatment that he had resorted to. As soon as he took charge of the case he ascertained that the family had purchased a lemon meringue pie, and that all who had partaken of it, to the number of four, were sick. The baker at whose shop the pie was made was exonerated from all blame in the matter; and the only explanation that has been suggested for the presence of the aniline dye in the meringue is that it was put in by a workman who had had a quarrel with one of his companions at the bakery, and who had been heard to say that he "would yet get square with him." This man is said to have sailed for Europe very shortly after the poisoning took place, and his whereabouts are now unknown.

—Mr. Bergh, the irrepressible president of the Society for the Prevention of Cruelty to Animals, has had introduced into the legislature a bill making vivisection under any circumstances a misdemeanor; accompanying it with a memorial which sets forth, among other things, that "divers learned and scientific (but misguided) medical men have perverted the meaning and intention" of the act passed in 1867, which provides that the laws previously made for the prevention of the infliction of unnecessary suffering upon the brute creation shall not be construed to prohibit or interfere with any properly conducted scientific experiments or investigations, which shall be performed only under the authority of the faculty of some regularly incorporated medical college of the State. The memorial goes on to say that these learned and scientific, but misguided, medical men, "under the pretense of demonstrating to medical students certain physical phenomena connected with the functions of life, are constantly and habitually in the practice of cutting up alive, torturing, and tormenting divers of the unoffending brute creation, to illustrate their theories and lectures, but without any practical or beneficial result either to themselves or to the students; which practice is demoralizing to both, and engenders in the future medical practitioners a want of humanity and sympathy for physical pain and suffering, which will greatly deteriorate their influence in their future professional life." It then makes the refreshing statement that "this matter of vivisectioning animals for so-called scientific purposes has been the subject of discussion and universal condemnation by the more eminent members of the medical profession in Europe," and finally calls upon the legislature to "wholly suppress this barbarous and unjustifiable sacrifice of animal life and infliction of unnecessary physical pain, suffering, and death upon the brute creation."

In commenting on the above, one of the daily pa-

pers very sensibly remarks that Mr. Bergh will gain nothing in his crusade against vivisection by thus misrepresenting the case, and that the statute of 1867, which he cites in his memorial, is a very discreet and well-considered enactment; providing all reasonable safeguards against the abuse of vivisection, as it does, without forbidding its legitimate use. The value of vivisection, it continues, is a question for experts, and there is no reason to believe, nor does Mr. Bergh make any effort to show, that it is resorted to when the same end might be gained by other means. In other words, there is no reason why the law should be altered.

— Ex-Governor Horatio Seymour has been in Albany lately, making an appeal to the Ways and Means Committee for an appropriation to aid in the suppression and stamping out of infectious and contagious diseases among cattle.

— An inmate of the Female Insane Asylum on Blackwell's Island has died from the effects of a fracture of the skull, which was caused by a blow with a wooden pail in the hands of a fellow patient. The occurrence took place at night in what is known as the "retreat," where the most violent patients are confined, and it could, no doubt, have been avoided if there had been a sufficient number of nurses on duty, or if the building, like all those under the care of the commissioners of charities and correction which are used for the insane, had not been so overcrowded. Dr. A. E. MacDonald, who is the temporary superintendent, and has charge of the asylum on Ward's Island in addition, in his statement to the coroner investigating the case, said that there were about two hundred patients in the retreat, and that they were in charge of eleven nurses in the day-time, but only one nurse (who is assisted by three prisoners from the work-house) at night. He also stated that, unlike the state asylum at Binghamton or private institutions, the authorities were compelled by law to receive all the patients sent to them, and, as the present buildings were entirely inadequate to accommodate them all properly, they were obliged to put patients in the same rooms in many cases where this was by no means advisable. Immediately after the occurrence Dr. MacDonald asked for more night nurses, a request which was at once granted by the commissioners, although the salary account was already overdrawn; but he said he would like to have six on duty every night, one for every ward, and to do away entirely with the system of employing work-house women to assist them. Within the past year or two several cases of a similar nature have occurred in the Lunatic asylum on Blackwell's Island, and it is now proposed to make a searching inquiry into its condition and management. The principal cause of trouble will probably be found to be in the insufficiency of the present appropriations to provide adequately for the proper care of such a large number of insane as are now in the institutions belonging to the city. At the inquest in the above case the Neurological Society asked the privilege of being represented by Dr. E. C. Spitzka, a request which, after some objection

by Dr. MacDonald on behalf of the asylum authorities, was acceded to by the coroner. The following is the letter addressed to the latter: "Sir,—The undersigned, the committee of the New York Neurological Society on Asylum Abuses, have learned with great satisfaction that you have resolved, in your official capacity, to inquire thoroughly into all the circumstances connected with the recent homicide in the City Lunatic Asylum on Blackwell's Island. Believing that we are in possession of much information relative to the proper management of insane asylums, the defects which exist in the system under which the asylum on Blackwell's Island is conducted, and the fitness of its officers for their duties, we respectfully request that you will, in the interests of justice and insane-asylum reform, permit a representative of the Neurological Society to assist you in your important investigation." The communication bore the signatures, among others, of Drs. E. C. Seguin, Wm. A. Hammond, and T. A. McBride. Dr. MacDonald objected on the grounds that the society, not being chartered, and having no legal standing, had no right to be represented at the inquest, and that its members were at a direct issue with him, being his personal and official enemies. He then stated that he had no desire to have anything concealed, and explained that he had been superintendent only two months, and had accepted the position very reluctantly. He was placed in charge, he said, for the purpose of correcting, if possible, certain abuses which were acknowledged to exist, and he was only too willing to have them exposed. They were the results of years of mismanagement, and he thought it unreasonable to expect that they should all be corrected in two months.

—The Rev. Edward Cowley, who was deposed from the management of the "Shepherd's Fold" on account of the legal action of the Society for the Prevention of Cruelty to Children, has been indicted by the grand jury for his ill-treatment of the inmates of that institution, and committed to the Tombs in default of twelve thousand dollars bail. In the proceedings on behalf of the above society to procure the removal of the children from the Shepherd's Fold, a number of the older ones testified to the filth, cold, hunger, and harsh treatment to which they had there been subjected, and a special investigation was made of the case of a little boy named Louis Victor, who was sent from the institution to St. Luke's Hospital. The house-physician of this hospital described in court his deplorable condition when admitted, and said that the child cried incessantly for food, especially meat, while he seemed not to have mental power to think of anything but eating. He stated that he could find no evidence of constitutional disease in the boy, as was claimed by the manager of Shepherd's Fold, and that he was convinced that his condition was due to "want of proper food, both as to quality and quantity." Dr. Abram Jacobi also testified that he had examined Louis Victor, and that he was firmly of the opinion that his condition was the result of starvation. Then Dr. Frank H. Hamilton testified that the ulcers on the child were of the character

known as "starvation ulcers," and Dr. J. Lewis Smith corroborated the statements of the others, while Dr. Edward C. Spitzka expressed his belief that the child's mind would probably never recover from the shock which it had suffered in consequence of the poor and insufficient food which he had been obliged to live upon.

— On the evening of February 4th there was opened, under the management of Mr. Steele Mackaye, the new Madison Square Theatre, which is claimed to be a model place of amusement in every respect, and in the fitting up of which great care has been taken and much money expended. The appointments are all of the most elegant description, and the ornamentation in the most approved style of decorative art, while, in addition to other special features, such as the double stage, the theatre has been provided with ample means of exit in case of fire, and the most complete system of ventilation of any such building in the country. All the lights are inclosed in plate-glass lanterns, each having a separate flue to carry its gas or smoke to the roof, and under all the seats in the orchestra and dress circle there are the openings of four-inch pipes, through which an immense circular pan in the basement is made to force either hot or cold air. It is asserted that with the system adopted, which is said to be the invention of Mr. Mackaye himself, the whole interior atmosphere can be replaced by pure air every ten minutes.

Correspondence.

A DAY IN NEW YORK.

MR. EDITOR, — There is probably no one sight with which the medical visitor to this city would be more interested or entertained than a glimpse into the interior of the house, during "office hours," of that apostle of orthopaedic surgery and the present head of our national association, Dr. Sayre. The house itself is conveniently situated on a Fifth Avenue corner, a wing, or rather an additional house, on the side street being devoted to professional purposes. The guest is immediately shown past a room full of expectant patients and up a short flight of stairs, and without ceremony is ushered immediately into the professor's sanctum. Original as the owner is himself, it is not likely that the visitor's attention will be wholly diverted from the apartment, which is altogether unique. It may be said to occupy the entire interior of the building, which for three stories has been eviscerated to construct a very effective and capacious library. On the level of each row of windows it is encreased by an iron gallery, the three tiers thus formed being reached from the polished hard-wood floor by a graceful spiral staircase in one corner. Books in solid columns extend from the floor to the ceiling, while from the iron-work hang at every available point oil-paintings, portraits, photographs, testimonials, and water-colors, many evidently of a high order of merit. A low mantelpiece and paneled mirror, opposite which stands a large library table, give an air of cosiness and comfort to the apartment, while the corners are occupied by apparatus showing it to be devoted not only to literature, but to that art also in which its owner excels.

From a beam roughly thrust through a corner of the balcony hangs the well-known suspension apparatus, and near by, in place of ancient breast-plates which one might look for in this antique hall, we find the gauze and plaster trophies of many a more modern victory lying about in picturesque confusion. A young Hibernian knight, whose portrait will soon find its way to your columns, has just donned his armor as we enter, and is proudly stepping off with an elastic gait to which the little fellow has not for a long time been accustomed, while the professor gazes at him with almost paternal pride, giving his locks such a turn with the brush as will set off his jury mast to the best advantage. We need hardly say that our greeting was a cordial one, that room was made among a knot of medical visitors, and that the case was explained with an enthusiasm which, as you well know, is characteristic of our veteran host. Do not imagine that this is a public clinic, for in another corner is ensconced an English clergyman or "rector" with his little boy, and opposite him a "gent" just arrived from the West this morning to have his "jacket" inspected, which, by the way, was put on nearly a year ago; it has been cut down the front and bound with leather, hooks having been also inserted for a lacing, and is still in excellent condition. These cases disposed of, a young girl is brought in with an extreme lateral curvature; when first taken in hand the lower right ribs rested nearly upon the prominence of the buttock. The method adopted by Professor Sayre in this case is, we believe, entirely new. The plaster jacket is applied while the patient suspends herself by the pulleys. In a few weeks the jacket no longer hugs the prominent ribs; this part is then cut away and a new piece applied, holding the advantage thus gained. This process is repeated frequently, so that on the visit in question a nearly symmetrical jacket had been obtained. It might be supposed that an entirely fresh bandage would be preferable to the partial change; this, however, is not the case, but we will not anticipate what its originator may have to say upon the subject. The rapidity, the ease, and the skill with which Dr. Sayre, assisted by his two sons, whips off an old bandage and replaces it with a new one is an instructive lesson. There is a decided "boom" about the place which many of those disposed to criticise or smile at some of Dr. Sayre's ways would do well to imitate.

On Fifteenth Street, a few doors from Fifth Avenue, stands the new New York Hospital. At a little distance it has the appearance of a neat set of "chambers." It bears, however, the name of no saint, but is simply dedicated to the "down-town poor of the great city." Beneath a broad, low archway a flight of steps leads one into the centre of the building. Once inside, we find the stern simplicity of a hospital, but further inspection reveals the fact that there are many luxuries not often found in such a place: the neatly tiled floors, the brass gas bracket behind each bed, the cranes which swing out from the wall over the bed to lend a helping hand to the occupant. The most noticeable feature is the "polarium," a sort of winter garden, filled with tropical plants and tanks of fishes, where patients may lounge and smoke, and enjoy the fine view of the city lying beneath them. The operating theatre is small, and the light, as is so often the case, arranged so that the operator must place himself between the patient and the class to see well; but the members of the staff are at pains to inform you that for this and many of

the unusual luxuries the trustees are responsible. The antiseptic treatment of wounds is in vogue, though all the details laid down by Lister are not carried out. We find the dressings, but not the spray. Dr. Markoe uses a long drainage tube, the ends of which project through the dressing, and through which a weak solution of carbolic acid is injected every four hours. Although this hospital is built on the old plan, its general sanitary condition is said to be good, and it undoubtedly serves a useful purpose from its central situation. It is in communication with the lower part of the city by means of ambulances, which dash through the streets at great speed, and have the right of way before every other vehicle, not excepting those of the fire department.

LETTER FROM NEW ORLEANS.

THE AUXILIARY SANITARY ASSOCIATION.

MR. EDITOR.—The year 1879 was unexampled in the sanitary history of our city, and a striking contrast to the preceding year. The total mortality for 1879 was 5122, — less than half that of 1878. Estimating our population at 210,000, this would give a ratio of 24.39 per 1000, — not a bad showing for a large city in a semi-tropical latitude with malarious proximities. The mortality for the whites was 3267; and, estimating the white population at 155,000, we have a ratio of 21.07. The colored population is estimated at 55,000, while their mortality was 1855, giving a ratio of 33.72 per 1000. In 1878 the ratios were 52.01 for the whites and 41.01 for the colored, with the same estimate for respective numbers of population; while, eliminating yellow fever mortality, the ratios per 1000 would have been 27.09 for whites and 37.69 for colored. It is apparent, therefore, that some cause apart from yellow fever must be sought to account for so great a difference.

The epidemic of 1878 could not fail to make a profound impression on our citizens, and, on the approach of warm weather in 1879, some of our most intelligent and liberal men became convinced that further action was demanded beyond what the constituted authorities were able to undertake. The city government appropriated only \$10,000 for the use of the board of health to carry out its work of house-to-house inspection with abatement of nuisances, — a sum inadequate to meet the salaries of sanitary inspectors and sanitary police, and leaving nothing for disinfectants, in case of need, or for sanitary improvements. The outcome of the situation was the formation of a voluntary organization of citizens, who incorporated themselves under our general laws, taking the title of "the Auxiliary Sanitary Association of New Orleans."

A call for a mass-meeting was issued March 31st, and the same night the association was organized. Over two hundred gentlemen soon were enrolled as members, subscriptions were solicited, and collections were made during the season amounting to more than \$35,000, of which somewhat more than \$32,000 were expended. Some of the principal results of this expenditure were the following: Ten sanitary policemen were furnished the board of health for four months, to aid in the annual house-to-house inspection. During the summer a rapid inspection of the city was made by the combined force of the association and the board of health, for the purpose of disinfecting all privy vaults

and causing a general cleaning up of yards, alleys, and private inclosures. A disinfectant solution consisting of zinc and iron chlorides was distributed at one hundred different points throughout the city, and offered gratuitously to all who would apply for it. Nineteen covered garbage carts and three garbage boats were supplied to the city authorities, and the practice of filling low lots with kitchen offal and dead animals was discontinued.

It may be added that the members of the association feel so much encouraged by the improved health of our city that they have no intention of disbanding. They propose now to raise \$100,000 for the present year, by forming a list of property owners, assessing them for such contributions as they are supposed to be able to make, and then collecting what they can. The assessment will be made for about \$150,000, with the idea of realizing something like two thirds. Their grand object is to provide a sufficient volume of water from the river to wash out the street gutters and the drainage canals often enough to remove accumulation of mud, and prevent stagnation and foul odors.

I may have mentioned in a previous letter that our natural drainage is from the bank of the river back to Lake Pontchartrain, four miles away. The river runs upon a ridge produced by its own deposit during the high stage, and the lower country is protected from overflow by artificial embankments, called *levees*, on both sides. In New Orleans there are no sewers, but the drainage is effected by open gutters into several large drainage canals in the rear of the city, which discharge into the lake. The flow of water is aided by large undershot wheels, driven by steam-engines, which lift the water over protection levees in the rear. These levees are required to protect the city from storm tides from the lake during the prevalence of northeast winds.

Now, the plan of the Auxiliary Sanitary Association is to lay a large pipe, built of cypress wood with strong iron hoops, along the front of the city, five miles in length. This pipe will have outlets into all the gutters of streets perpendicular to the river, and will be supplied by three powerful steam pumps from the river during the ordinary stage of water. In time of high water it will be necessary only to open sluices through the levees, as is done already in some places for this purpose. It is estimated that the cost of this pipe, twenty-two inches in diameter, built of cypress stuff, two and a half inches thick, will be \$1.50 per foot, or \$39,600 for 26,400 feet; and the cost of the pumps, with boilers and engines complete, \$18,000. This system of cleansing the gutters and canals will therefore cost \$57,600 for original outlay, while the running expense will be far less than the old plan of cleaning the gutters by hand-work with spades followed by carts, and a periodical excavation of the canals by dredging machines, and it is expected that the result will be much more satisfactory.

In addition to the sanitary work already mentioned, the infected portion of the city (where most of the cases of yellow fever occurred in 1879), comprising about forty squares, underwent a repeated process of cleaning up and disinfection during the month of September. Garbage and rubbish of all kinds were removed, lime was scattered freely in street gutters, and a strong solution of copperas was thrown into all privy vaults and cess-pools. The cost of this work was paid by the National Board of Health.

It might be unwarrantable to attribute our escape from another epidemic in 1879 wholly to improved sanitation. The preceding severe winter should probably be allowed some credit, but that did not avail for the protection of Memphis, nor prevent a wide-spread visitation of Southern Louisiana. Candor requires the acknowledgment that we are ignorant of some of the causes that govern the origin and spread of yellow fever, as we are in case of typhoid and scarlet fevers. Yellow fever did not seem to have, last summer, in New Orleans an epidemic disposition, just as, at the present time, is the case with scarlet fever and diphtheria, which exists in a sporadic form. S. S. H.

NEW ORLEANS, January 27, 1880.

COUNTRY PRACTICE: LEAD POISONING.

November 26, 1879. S. L., age fifty-eight years. Patient had nausea, tenderness of mouth and swelling of gums, slight diarrhoea, pains in abdomen and chest, and leaden-colored lines along the mucous membrane bordering the teeth. The breath was offensive, the odor like that produced by salivation from mercury. Soon the whole cutaneous surface became intensely yellow, changing to a copper hue. This had considerably faded before death. Skin dry; urine scanty and of the color of saffron; micturition difficult; tender-

ness and pain in region of liver. Later there was constipation, with very severe pain in abdomen, chest, arms, and legs. Then came paralysis of arms and legs, most complete on right side; feet swollen, right more than left; an abscess in right hand, with bad pus; three small abscesses on right leg. Temperature never above 101° F.; usually nearly normal, or a little below.

Diagnosis: lead poisoning. *Treatment:* iodide of potassium, laxatives, and generous diet. Patient died December 30th. No post mortem.

Remarks: Though lead poisoning was suspected on the first visit, yet its source could not be ascertained until two weeks before death. The physician then found that the patient and others of the family had been drinking cider from a tub that had been painted inside with white lead and oil a few months before. Of course the impurity was unknown to the physician, until he accidentally learned of the painted tub.

Other members of the family had characteristic condition of gums, nausea, neuralgic pains in chest and abdomen, but no paralysis or hepatic disturbance.

Query: What relation had the lead poisoning to the jaundiced condition of the skin and urine? The liver was not larger, but rather smaller than normal.

WILLIAM CHILD.

BATH, N. H., January 20, 1880.

Two thousand two hundred and forty-three deaths were reported; 881 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 463, consumption 366, lung diseases 295, diphtheria and croup 205, scarlet fever 80, typhoid fever 38, diarrhoeal diseases 35, measles 33, whooping-cough 29, erysipelas 19, malarial fevers 13, cerebro-spinal meningitis seven, small-pox four. From *measles*, New York 24, Chicago five, Brooklyn two, Pittsburgh and New Haven one. From *whooping-cough*, New York seven, Brooklyn, Boston, Cleveland, and Pittsburgh three, Baltimore and District of Columbia two, Philadelphia, Chicago, Cincinnati, Newburyport, Fitchburg, and Weymouth one. From *erysipelas*, New York six, Brooklyn five, St. Louis two, Philadelphia, Boston, District of Columbia, Cleveland, Worcester, and Cambridge one. From *malarial fevers*, New York five, Brooklyn three, Chicago two, St. Louis, Baltimore, and Milwaukee one. From *cerebro-spinal meningitis*, Chicago and Cincinnati two, Charleston, Worcester, and Fall River one. From *small-pox*, Philadelphia and Worcester two. Sixty cases of measles, 51 of diphtheria, and 33 of scarlet fever were reported in Brooklyn; diphtheria 26, scarlet fever 11, in Boston; diphtheria 19, scarlet fever seven, in Milwaukee; diphtheria 12, in New Bedford. During January diphtheria was the most prevalent infectious disease in New York.

Allowing for New Orleans, not reported, the total number of deaths and of deaths under five are very nearly the same as for the previous week. Lung diseases, consumption, diarrhoea, and especially typhoid fever caused more deaths, scarlet fever fewer; other diseases remain without noteworthy change. Scarlet fever is reported as being more malignant in Cleveland. Since the appearance of small-pox in Worcester, two months ago, up to date there have been 22 cases of small-pox and varioloid, all *unvaccinated* except two. The death-rate of whites in the District of Columbia was only a little over one third of that of the colored population. In 37 cities and towns of Massachusetts, with an estimated population of 988,610 (population of the State about 1,690,000), the death-rate was

20.41 against 20.17 and 20.58 of the previous two weeks, with a somewhat increased mortality from diarrhoea and typhoid fever.

For the week ending January 17th, in 142 German cities, with an estimated population of 7,648,478, the death-rate was 26.2 against 27.7 and 27.2 of the previous two weeks. Three thousand eight hundred and forty-eight deaths were reported; 1700 under five; pulmonary consumption 528; acute diseases of the respiratory organs 426, diphtheria and croup 155, scarlet fever 73, whooping-cough 58, typhoid fever 39, measles and *rötheln* 36, puerperal fever 20, small-pox (Cologne and Bremen), two, typhus fever one. The death-rates ranged from 14.1 in Götting to 38.0 in Dantzig; Königsberg 26.1; Breslau 29.2; Munich 34.4; Dresden 20.8; Berlin 25.5; Leipzig 26.2; Hamburg 27.9; Hanover 17.5; Bremen 22.8; Cologne 26.8; Frankfurt 21.1; Strassburg 37.2. For the same week, Vienna 28.5; Prague 37.5; Paris 33.2. Small-pox and diphtheria continue very prevalent in Paris. In the 20 chief towns of Switzerland acute diseases of the respiratory organs were widely prevalent and fatal; the infectious diseases except diphtheria caused very few deaths. In Belgium small-pox was the most prevalent and fatal of the zymotic diseases, being chiefly confined to the smaller towns, typhoid fever coming next in order, diphtheria being almost absent; lung diseases caused very great mortality.

For the week ending January 24th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 26.0 against 24.2 and 24.0 of the previous two weeks. Three thousand seven hundred and forty-one deaths were reported: diseases of the respiratory organs 559, whooping-cough 198, scarlet fever 145, measles 129, diarrhoea 28, fever 24, diphtheria 17, small-pox (London) three. Under the milder temperature there was a considerably increased mortality from whooping-cough and lung diseases. The death-rates ranged from 19.6 in Oldham to 30.7 in Manchester; London 27.1; Brighton 20.9; Bristol 23.7; Liverpool 28.3; Birmingham 25.1. In Edinburgh 21, Glasgow 26, Dublin (small-pox caused five deaths) 40.

The meteorological record for the week in Boston was as follows:—

A PROPOSED ACT TO REGULATE THE PRACTICE OF MEDICINE IN MASSACHUSETTS.

Be it enacted, etc. SECT. 1. The governor, with the advice and consent of the council, shall appoint from the members of medical societies in the commonwealth, incorporated with power to examine candidates for membership and to approve their members, eight discreet persons, learned in the science of medicine and graduates of an approved medical institution, with one discreet practitioner of dentistry, as a board of medical registration; three of whom shall serve for one, three, and five years, respectively, as may be arranged by lot after their appointment. Vacancies occurring by expiration of the term of service of members shall be filled by the appointment of new members for the term of five years. The selection of members of said board from said societies shall be so made that the number of members of each society serving thereon shall be, as nearly as possible, proportional to the whole number of members of such society living in the commonwealth; provided, however, that there shall always be upon said board one practitioner of dentistry, and at least one member of each of said societies, so long

as it has thirty or more members, and upon the board as first appointed an additional member from each society having one hundred and fifty members. Any member of the board may be removed at any time, for sufficient cause.

SECT. 2. The board may elect a president from their own number, and a secretary who may but need not be a member, and who shall receive for his services such portion of the fees collected by the board as they may determine. The necessary expenses of the board, and of the members while actually engaged in their official duties, shall be paid from the fees hereafter provided, and any surplus of fees not expended for the purposes above named shall be paid into the treasury of the commonwealth annually.

SECT. 3. The board shall meet at least twice at Boston, once at Worcester, and once at Springfield, in each year, for the examination of applicants as hereinafter provided; the first meeting at each place to be held within three months after their appointment.

Notice of such meetings, specifying the purposes for which they are held, and containing a reference to this act, shall be published not less than three times in one newspaper in each

county. At such meetings any applicant not less than twenty-one years of age, of good moral character, shall, on payment of fifteen dollars therefor, be examined by the board in such subjects as they may deem necessary, not including therapeutics; and any applicant who has studied medicine three full years, and has received the degree of doctor of medicine, or a license to practice medicine, from an approved institution having power to grant the same, shall receive a license to practice medicine within the commonwealth, if found qualified therefor.

SECT. 4. Any person who at the time of the passage of this act is a member of any society described in section one may practice medicine without further license so long as he remains a member of either of said societies; and any person of good moral character who has received the degree of doctor of medicine, or a license to practice medicine, from an approved institution having power to grant the same, and who has practiced medicine within the commonwealth for one year before the passage hereof, shall be entitled to a license to practice medicine upon payment of two dollars therefor. The board may also grant a license, without examination, to any person of good character and reputation who has practiced medicine within the commonwealth for ten consecutive years on payment of two dollars; and to any person of good character and reputation who has so practiced for two consecutive years, and who is found qualified therefor after an examination in such subjects as are agreed upon by all the members of the board, on payment of fifteen dollars.

SECT. 5. A license may be granted, without examination, to any practitioner of medicine not residing in the commonwealth, of good character and reputation, who has received the degree or license mentioned in section three, on payment of two dollars; and a temporary license for a period not exceeding three months may be granted, without examination, to such person, on payment of two dollars. A temporary license to render gratuitous medical services under the direction of his instructor or superior officer may be granted, without examination, to a student of any incorporated school of medicine in the commonwealth who has studied medicine not less than two years, or to a student of medicine or dentistry employed in a public hospital or dispensary, on payment of one dollar.

SECT. 6. A license to practice midwifery may be granted to any person not less than twenty-one years of age, of good character and reputation, who, on examination by the board, is found qualified therefor, on payment of five dollars.

SECT. 7. A license to practice dentistry shall be granted to any applicant not less than twenty-one years of age, of good moral character, who has studied medicine or dentistry three full years, and has received the degree of doctor of medicine, doctor of dental medicine, or doctor of dental surgery from an approved institution having power to confer the same, and who on examination by the board is found qualified therefor, on payment of fifteen dollars; and such license shall be granted to any person of good character and reputation practicing dentistry in the commonwealth at the time of the passage hereof, on payment of two dollars.

SECT. 8. It shall be the duty of every applicant for a license hereunder to furnish to the board satisfactory evidence of his qualifications therefor or right thereto, as hereinafter provided. The board may refuse a license to any person who has been convicted of crime; and if any person holding a license shall be so convicted, or shall, in the unanimous judgment of the board, cease to be qualified therefor in accordance with the provisions hereof, such license may be revoked; and a license obtained by fraud or false representations shall be void.

SECT. 9. Nothing herein shall be construed to forbid the practice of medicine by medical officers in the service of the United States, the treatment of a ship's company by its surgeon, the rendering of medical services by a non-resident, duly authorized to practice medicine in the place where he resides, in any case wherein he is called into the commonwealth by any person residing therein for the purpose of rendering such services, nor the gratuitous rendering of medical services by any person in case of emergency; provided that it shall not be necessary to negative these exceptions in any complaint or indictment hereunder. The word "medicine" herein shall be construed to include surgery and midwifery.

SECT. 10. No certificate of death shall be received or recorded by any town or city clerk or registrar unless the same is signed by a person duly licensed or authorized to practice medicine, as herein provided.

SECT. 11. Any person who shall practice or shall in any manner publicly offer or advertise to practice medicine or dentistry within the commonwealth, without being duly licensed or authorized thereto, as herein provided, shall be punished by fine not exceeding five hundred dollars.

SECT. 12. For the purpose of the appointment of the board

of medical registration, and of all proceedings by them hereunder, this act shall take effect upon its passage, and shall take full effect on the first day of October next.

The board shall on or before the first day of January of each year return to the secretary of the commonwealth the names of all persons licensed or authorized to practice medicine, dentistry, or midwifery.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM FEBRUARY 7, 1880, TO FEBRUARY 13, 1880.

TAYLOR, M. K., captain and assistant surgeon. To repair to Washington, D. C., and settle his accounts with the treasury department. On completion of this duty, rejoin his proper station. S. O. 30, A. G. O., February 7, 1880.

MCLELLERY, H., captain and assistant surgeon. Relieved from duty in Department of the East, to proceed on or before March 1, 1880, to Fort Omaha, Nebraska, and report in person to commanding general, Department of the Platte, for assignment to duty. S. O. 29, A. G. O., February 6, 1880.

HOFF, J. V. R., captain and assistant surgeon. To report in person to commanding general, Department of the East, for assignment to duty at Fortress Monroe, Va. S. O. 29, C. S., A. G. O.

HALL, WILLIAM R., first lieutenant and assistant surgeon. The leave of absence granted him December 5, 1879, from headquarters, Department of the Columbia, is extended three months. S. O. 32, A. G. O., February 10, 1880.

APPEL, D. M., first lieutenant and assistant surgeon. So much of the order of December 29, 1879, as relieved him from duty in Department of the Missouri is revoked. He will report in person to commanding general, Department of the Missouri, for assignment to duty. S. O. 32, C. S., A. G. O.

BOOKS AND PAMPHLETS RECEIVED.—A System of Medicine. Edited by J. Russell Reynolds, M. D., F. R. S., Fellow of the Royal College of Physicians of London, etc. With numerous additions and illustrations by Henry Hartsorne, A. M., M. D., Fellow of the College of Physicians of Philadelphia, etc. In three volumes. Vol. I. General Diseases and Diseases of the Nervous System. Vol. II. Diseases of the Respiratory and Circulatory Systems. Philadelphia: Henry C. Lea. 1879.

We refer to this important work now only for the purpose of recommending it to those of our readers who may be in need of a complete treatise on British and American Medicine, as we shall take a later opportunity of calling attention to many of the chapters which deserve especial commendation. The English edition of five volumes is reduced by skillful economy of space to three very handsome ones, with a great reduction in cost. The work is published by subscription, and an agent, Mr. French, is at present calling upon the practitioners of New England, whom we have no hesitation in advising to buy it.

Partial Forward Dislocation of the Head of the Humerus, or Backward Displacement of the Tendon of the Long Head of the Biceps, replaced after the Lapse of One Month. By David Prince, M. D., Jacksonville, Ill. (Reprint.)

Pay Hospitals and Paying Wards throughout the World. Facts in Support of a Rearrangement of the English System of Medical Relief. By Henry C. Burdett. London: J. and A. Churchill, New Burlington Street, W. 1879.

INTESTINAL OBSTRUCTION.

WITH A REPORT OF SIX CASES.¹

BY WILLIAM B. DAVIS, A. M., M. D.,

Professor of Materia Medica, Mount Medical College, Cincinnati.

It is my privilege this evening to present the society with a report of six cases of intestinal obstruction, which have fallen under my personal observation. These obstructions were within the bowel or in the walls of the intestines. It is well known that the chief characteristics of obstructions of this kind are pain, chiefly about the umbilicus or right iliac region; constipation; vomiting, which may become feculent; distention, which may be general or confined to a portion of the abdomen; hiccup, which usually appears late, but may manifest itself early when the obstruction is high up; suppression of urine, and collapse. Arrest of urine may occur, according to Sedgwick, if the attack be sudden and acute, and implicate the small intestines; or it may be produced by the vomiting, fever, local inflammation, and collapse. In addition to the above symptoms we are likely to observe in invagination of the bowel frequent desire to go to stool, tenesmus, and discharge of blood.

Feculent vomiting, according to Professor Macleod,² of the University of Glasgow, is the only certain sign of obstruction. Leichtenstern³ states that an obstruction of the intestine may remain latent for a long time, and then suddenly appear with the severest indications, and that there is no cause of acute obstruction which cannot spontaneously disappear as well as originate. "Nevertheless," he says, "the number of these spontaneous cures is exceedingly small when compared with the mass of cases that have ended fatally, and we must describe the prognosis of internal occlusion of the intestine as in the highest degree unfavorable, and ileus as — to use De Haën's words — a *morbus terribilis, ereberrime letalis*."

The duration of acute obstruction of the bowels is stated to be on the average six days, and varies from eight hours to thirteen days. The most common termination is by general peritonitis. In twelve thousand necropsies, Brinton⁴ found one in every two hundred and eighty deaths to be from obstruction of the bowels, hernia excluded. Leichtenstern's investigations led him to the conclusion that in every three or four hundred deaths one was from obstruction of the bowels.

Concerning the percentage of recoveries there are but few reliable data to be found. The General Hospital of Vienna reports sixty cases of ileus, of which about eight per cent. recovered.

CASE I. OBSTRUCTION FROM INTUSSUSCEPTION.

F. R., aged five months, a large and vigorous child for his age, was suddenly seized, on the morning of May 22, 1879, with violent pains in his bowels, characterized by sharp agonizing cries, limbs flexed on abdomen, severe and almost continued tenesmus, and discharges of mucus and blood. The mother said the child had passed a comfortable night, and seemed perfectly well up to seven o'clock in the morning. I saw him at

¹ Read before the Cincinnati Medical Society, January 13, 1880. See Report of Proceedings on page 201.

³ Ziemssen, vol. vii. page 518.

⁴ Intestinal Obstruction, page 33.

nine A. M., and ordered a tablespoonful of castor-oil to be administered and hot fomentations to be applied over the abdomen. Three P. M. No passage from bowels; more quiet, but straining continues, with some discharge of blood and mucus. Seven P. M. No passage; other symptoms about the same, except that the child shows signs of collapse. I was now convinced that I had a case of invagination to deal with, and sent for Dr. John Davis. He corroborated my diagnosis, and we at once placed our little patient in an inclined position, with pelvis raised and trunk dependent, and with the aid of a "fountain syringe" filled his bowels with a quart or more of warm water. We then applied a compress over the anus, in order to prevent the escape of the fluid, and occasionally lifted him by his legs, and, with body dependent, gave one or two quick jerks; then gently kneaded the bowels. Some of the water escaped during our manipulations, but not much. At eleven P. M. we introduced more warm water into his bowels, and as the child was in a state of collapse we directed him to be wrapped in blankets, with warm bricks closely applied, and left, not expecting him to survive the night. On the morning of the 23d we found him alive, warm, perfectly blanched, very quiet, but no operation, not even the discharge of the water we had injected. We ordered small doses of beef tea and wine to be given him. At three P. M. that day the child had a copious feculent passage, and after that slowly rallied, until he was restored to perfect health.

CASE II. OBSTRUCTION OF DOUBTFUL ORIGIN.

J. E., aged forty-three years, born in Germany; occupation, saloon-keeper. Very obese, weighing near two hundred and fifty pounds. During the past two years he has had several severe attacks of inflammatory rheumatism, and for the three months immediately preceding his last illness he was a great sufferer from rheumatic gout. On the evening of September 19, 1879, he informed me that he was suffering from a pain in his stomach and bowels, which had annoyed him for several days. As he had been troubled before with indigestion and acid stomach, I thought this attack might be of a similar character, and ordered some pepsin and soda for him, and also prescribed a mild aperient. September 20th, ten A. M. He passed a very uncomfortable night, having constant pain in right hypochondriac region, with more or less distention of the bowels. He had several small, watery stools, but felt in no way relieved by them. Pulse 100; temperature, 101° F. I directed morphia in one-eighth grain doses to be given every two or three hours, when in pain.

September 21st. Pulse, 120; temperature, 102° F.; tongue dry and furred; urine scanty and high colored; bowels tympanitic and very painful; vomited everything taken into the stomach. Gave one sixth grain of morphia subcutaneously, and directed a nurse to give him copious enemas of warm water. Three P. M. No relief. Gave another injection of morphia, and repeated the warm-water enema. Seven P. M. Much worse; pain very agonizing; no operation; urine suppressed; entire abdomen distended to its utmost capacity. Called Dr. Falls and Dr. Clendenin in consultation. We inserted a large gum catheter, its entire length, into his bowels and injected three quarts of warm water, continuing the subcutaneous use of morphia, giving it often enough to keep him well under its influence.

September 22d. Pulse 100; temperature 99° F. Urine suppressed. Early in the morning he had a watery discharge, which had a slight feculent odor; ten A. M., he had another passage, which was more feculent in character; at one P. M. he had a passage of more consistence. His pain was almost gone, and the bowels were softer. His pulse was rapid and weak, and his surface suffused with a cold, clammy perspiration. We ordered brandy and beef tea to be given freely, but he rapidly sank, and died at three o'clock that day.

This man's habits of life and rheumatic attacks had so impaired his health that he had not sufficient vitality to resist any severe strain; hence he died. The obstruction was overcome, his bowels were moving, temperature falling, and pain almost gone.

CASE III. OBSTRUCTION FROM ULCERATION OF THE APPENDIX VERMIFORMIS.

J. B., aged twenty-one years, American, married, green-grocer, was a large, powerful young man, of active habits and robust health until his last illness. I was called to see him May 10, 1868, and found him suffering with severe pain in his bowels. He had not felt well for several days, but kept at his work until compelled to desist. His abdomen was very much distended and exquisitely painful in every part, and he had had no passage for several days. He had a high fever, with full, bounding pulse. His treatment consisted of full doses of opium and enemata of warm water. His pain was somewhat controlled, but there was no amelioration of the acute inflammatory symptoms, and he sank, and died on May 12th, without having had any movement from his bowels. Drs. John Davis and David Judkins saw him in consultation with me.

Autopsy. We made a post-mortem examination, and found acute inflammation of the peritoneal covering of the bowels, and the appendix vermiformis in a state of suppuration and almost detached from the cæcum, being held by but a small filamentous tissue. In the appendix we found a hard, dry, scybalous lump about the size of a pea. There was occlusion near the ileo-cæcal valve and distention above.

CASE IV. OBSTRUCTION FROM TWISTING OF THE INTESTINE.

Mrs. S., aged thirty, married, German; has three children. Her husband keeps a saloon, and serves a free lunch to his patrons every day. They employ no servants, Mrs. S. attending to her family and household duties and the preparation of the daily lunch. This often requires rapid work and severe exertion. On February 19, 1879, after the hurry of her morning's duties were over, she experienced a severe cramp, as she described it, in her stomach. She took some home remedy, without obtaining relief. The pain increasing and vomiting setting in, she sent for me at three P. M. I found her suffering with pain in her right hypochondriac region, with some distention of bowels, nausea, and vomiting. I ordered one eighth grain of morphia and five grains of bismuth, to be given her every hour until relieved. Six P. M. All of her symptoms intensified. Increased the morphia to one fourth grain every hour. Nine P. M. No relief; suffering very intense. She informed me that she felt a large lump in her right side. I examined, and found an enlargement in her right hypochondriac

region, which was perceptible to the eye as well as the touch. It was about the size of a hen's egg, and felt like a strangulated knuckle of intestine, being resonant upon percussion and painful on pressure. I injected over the protrusion and in the most painful locality one fourth grain of morphia, and directed her to send for me at twelve P. M. if she were in much pain. No messenger came, and I did not see her until the next morning at nine o'clock, February 20th. She then informed me that the subcutaneous injection gave her almost instantaneous relief; that she went to sleep soon after, and did not wake until morning, when she felt for her lump and found that it was gone. I could find no traces of it except some tenderness on pressure. She made a good recovery, and was discharged on the third day, after her bowels had been moved by a gentle purgative. She had never had any hepatic difficulty, and during this attack and afterwards there was no yellowishness of skin or conjunctiva, and no gall-stones were found in any of her passages. I have thought that this obstruction was occasioned by a spasmodic action or twisting of the bowel, probably in the upper portion of the ascending colon, and what Dr. Brinton calls "torsion of the bowel on its axis."

CASE V. OBSTRUCTION FROM FÆCAL IMPACTION.

Mrs. M., aged sixty-three years, American, married, was seen in consultation with Dr. Robert F. Carver. As I saw her she presented the appearance of an infirm, emaciated woman. She had been ill for a week with obstruction of the bowels, which Dr. Carver had diagnosed as impaction of feces. There was slight pain and much distention of the bowels, with some derangement of stomach, but no febrile disturbance. The abdominal parietes were so thin and flaccid that the colon could be clearly traced. The descending portion was much distended with impacted matter. By the aid of frequent enemata of warm water the impaction gave way, and she discharged enormous quantities of strawberry seeds, and made a good recovery.

CASE VI. OBSTRUCTION FROM PROBABLE ULCERATION OF APPENDIX VERMIFORMIS.

Mr. F., aged thirty-three years, Irish, teacher, married; florid complexion, nervo-bilious temperament, general health good. A compactly built, muscular man. On July 15, 1878, I was called to see him, and found him suffering from a severe pain in the region of the umbilicus and extending to the right iliac fossa. It yielded readily to opium treatment, and he left on the 17th to spend his vacation in the far West.

December 26, 1878, Dr. W. Wenning was called to see him at twelve P. M. He was suffering with excruciating pain in his bowels, attended with distention. Under treatment "the pain gradually descended to the right inguinal region, and persisted there. There was great tympanites, with tenderness on pressure, together with a feeling of a hard substance in the right iliac fossa."

On January 4, 1879, he called at my office, and I found him still suffering from a localized pain in the right inguinal region. "The hard substance" described by Dr. Wenning was very perceptible. He presented a haggard, anæmic appearance, and I placed him upon quinine and iron, and directed a fly-blisters to be placed over his "lump." His bowels

were kept open with simple laxatives. On this treatment he rapidly improved, and on January 22d he reported himself well.—every vestige of his lump having disappeared. I did not see him again until he called at my office Sunday afternoon, February 16, 1879, and asked for a prescription to control "pain in his stomach." He said he had been attacked with pain in the region of his umbilicus at four o'clock that morning, and had suffered more or less with it ever since. A friend had advised him to eat some garlic for it, and he had done so, but on his way to my office had vomited several times, and thought he had thrown it all off his stomach.

I directed him to take one eighth grain of morphia and five grains of bismuth every hour until relieved. I was summoned to his house that night at eleven o'clock, and found that he had obtained no relief whatever from his pain, but his vomiting had been controlled. His temperature was 98° F. and his pulse rate 74. I ordered him one fourth grain of morphia every hour when in pain.

February 17th. He slept most of the previous night, and was comparatively comfortable. Temperature normal and pulse 64. He complained of pain upon pressure in the region of the umbilicus, and percussion revealed a tympanitic condition in that locality. In answer to my questions, he said that he had eaten nothing unusual recently except a handful of raisins. He was regular in his bowels, and had had an evacuation from them on the morning of his attack which was somewhat costive in character. I ordered him three compound cathartic pills, to be followed with a copious enema of warm water. I saw him again at five p. m., and found that the enema had been discharged, but there was no passage from his bowels. He had vomited several times, and had constant, but not very intense pain. I directed another enema to be given, and if it did not operate by nine p. m. more morphia. At twelve o'clock that night I was sent for and informed that he was much worse. I directed the messenger to go for Dr. Gustaf Brühl, and request him to meet me at Mr. F.'s residence. We found him in great agony; bowels much distended and very painful, but severest pain about the umbilicus; tongue dry; urine scanty; temperature 100° F., pulse 85. We gave one fourth grain of morphia subcutaneously, and ordered five grains of calomel every three hours until fifteen grains had been taken. By the courtesy of Dr. Wenning, who lived near by, the morphia was again administered at four a. m. From this time Dr. Wenning joined us in the care of the case.

February 18th. Pulse 80, temperature 100° F., tongue dry and coated, pain severe, distention over whole abdomen, no passage. Rejects everything taken into the stomach. Continued subcutaneous use of morphia every four hours; also gave calomel in five-grain doses every three hours, and ordered copious enemata of warm water at five p. m. All of the above symptoms are intensified, and in addition hiccough and stercoraceous vomiting have set in, tongue dry and furred, urine suppressed, pulse 112, temperature 100° F. Continued the morphia injections and besides gave one twelfth grain with two grains of bismuth every two hours. We gave, beside, sulphuric ether and bicarbonate of soda in aq. laurocerasi.

February 19th. Much worse: eyes sunken, voice husky and weak, hippocratic aspect of face, surface

suffused with cold perspiration, urine suppressed. Hiccough and stercoraceous vomiting continue, with but brief intervals of rest. Pulse 120, temperature 102° F. Impending collapse was so apparent that the emphatic utterance of one of the physicians as we reached the consulting room, namely, "Our patient is a doomed man; he must die," was but the reflection of the thoughts of the others. Nevertheless, we determined to renew our efforts with more copious enemata with the addition of beef tea and brandy. Heretofore, the injections had been given by attendants, one of whom claimed to be skilled in their administration. [They were all rejected shortly after having been given.] We now decided to administer them ourselves, and in quantity sufficient to distend the bowels; hoping, thereby, to soften and dilute the feces and overcome the obstruction. We relied in our treatment upon the mechanical pressure of the water, the antispasmodic action of the warmth, and the nutrient and stimulant effects of the beef tea and brandy, in addition to the soothing and sustaining powers of opium. We passed a large elastic catheter its entire length into his bowels, and then slowly injected two quarts of warm water with four tablespoonfuls of beef tea and two of brandy. This quantity of water, beef tea, and brandy was injected at eleven a. m., two, five, eight, and eleven p. m., making in all ten quarts. This quantity he retained save about one quart, which was passed in the afternoon. He vomited after each enema, and the vomit was still feculent, and his hiccough continued at intervals. By five o'clock, p. m., a marked change for the better had taken place; pulse 116, full and strong, temperature 100° F. The face had a natural expression, and the skin was warm and moist.

February 20th. Pulse 100, temperature 98° F. Tongue moist; urine freely secreted; skin warm and moist; stomach somewhat irritable, but vomit no longer feculent; occasional hiccough; bowels distended and painful; no passage. He had slept most of the previous night, and was very hopeful and cheerful. Continued treatment, giving the enemata with beef tea and brandy at ten a. m., two, five, eight, and eleven p. m., ten quarts; of this he discharged at different times during the twenty-four hours about five quarts. At eight p. m. there was a feculent odor to some of the water discharged. There was also a marked improvement in all of his symptoms.

February 21st. Pulse 100, temperature, 98° F. Tongue clean, hiccough gone, urine free, vomit bilious, no passage; abdomen distended, with pain all over, but more acute in right inguinal region. We observed a circumscribed elevation a little to the right of the median line and just below the umbilicus, in which we thought we detected fluctuation on percussion. Continued treatment, giving the enemata at ten a. m., three and five p. m., three quarts in all. At half past three p. m. there was an unmistakable feculent discharge, the contents being hard, lumpy, and very offensive. This evening we allowed him some ice cream, which he relished and retained. This was the only article of food or drink which he had taken by the stomach for three days.

February 22d. Pulse 100, temperature 99° F. Does not feel as well. Eyes sunken, and general expression worn and haggard. Returned to large warm-water enemata with beef tea and brandy, giving them at eleven a. m., four and seven p. m., six

quarts. Before night he regained his lost ground. We allowed him some chicken tea and rice, which he retained and relished. During the day he had three feculent operations.

February 23d. Pulse 88, temperature 98° F. Tongue clean and moist; expression cheerful, spirits buoyant, bowels distended and tender. Had eight operations during the twenty-four hours; one of them was composed of hard, dry scybala, with very offensive feculent odor.

February 24th. Pulse 80, temperature 98° F. Eyes bright, countenance smiling, voice strong and cheery; no distention and no pain in bowels, except on pressure, and then only in right inguinal region, where a slight gurgling noise was observed on percussion, indicating, as we thought, chronic ulceration in the region of the appendix vermiformis, which, in our judgment, gave rise to the occlusion of his bowels.

The chief point of interest in this case was that we had a patient in a state of collapse, with dissolution imminent, from obstruction of the bowels, and we gave copious enemata of warm water, and the man lived. Now was the preservation of his life due to the warm water enemata? In our opinion it was. Did not the subcutaneous use of opium contribute to the preservation of his life? Yes, undoubtedly; although we say that with the free use of opium and without the warm-water enemata he would in all probability have died. The converse of this is also probably true. We have already indicated the theory upon which we based our use of the warm-water enemata, namely: (1.) The water acts mechanically by its volume in distending the intestines. (2.) By its warmth as an antispasmodic. (3.) As a solvent upon the impacted feces. (4.) As a vehicle for conveying nutrients, stimulants, and medicines into the system.

In this case our patient was at the point of death, and improved with the first copious injection of warm water, and continued to improve for three days under its free use. Then the injections were reduced from ten to three quarts, and in less than twenty-four hours he became worse, and upon the resumption of their copious use he immediately improved.

From the 19th to the 22d, inclusive, twenty-nine quarts of warm water were injected, and only ten quarts were discharged, before feculent operations occurred.

CONCLUSIONS.

Our observations and experience lead us to the following conclusions, namely:—

(1.) That the subcutaneous use of opium and copious enemata of warm water are the best treatment in most cases of intestinal obstruction.

(2.) That purgatives are not only useless, but injurious, as they only increase the already overexcited peristaltic action of the intestines.

(3.) That when the stomach is disturbed all nourishment and medication should be administered with the enemata, except opium, which is more efficacious as well as more prompt in its action when given subcutaneously.

I might stop here, but if your patience is not too severely taxed, it may be of interest for us to discuss very briefly the treatment recommended by modern authorities in obstruction of the bowels.

Opium. All late authorities are in accord as to the preeminent usefulness of this drug in all obstructions

of the bowels. Indeed, some insist that the exclusive use of opium is the only treatment necessary. Dr. Thomas Buzzard, who edited the excellent work of Dr. William Brinton on Intestinal Obstruction, publishes three cases, by way of editorial notes, in connection with that work, which he treated successfully with opium alone.

Dr. Hugh Owen Thomas, in the *Liverpool and Manchester Medical and Surgical Reports* for 1877, publishes a very exhaustive article, entitled, *On Past and Present Treatment of Intestinal Obstructions*, in which he takes strong grounds against the use of any and every form of medication but that of opium. He says "distention and pain are to be averted if possible, and when present diminished, if their complete removal is not possible. *The symptoms of constipation are to be ignored in treatment*, as the more prolonged the constipation the more fluid the evacuation when it does take place. . . . Where constipation had been well maintained by opium beyond the fourteenth day, the patient always passed liquid and pultaceous stools." He quotes Dr. Brinton in support of this, namely, "Nature herself is preparing within the obstructed bowels the best of all purgatives to accomplish whatever an aperient can do towards opening a passage." He is as unqualified in his denunciation of enemata as of purgatives. Concerning them he says, "Whether they be administered for the purpose of diagnosis, or supplying nourishment, or giving sedative medicines, or for mechanical purposes, even should they be but two or three ounces in bulk, they may again cause the recurrence of all the symptoms that the sedative medicine may have controlled. In the treatment of these affections they must be totally discarded in every form and for all purposes."

All authorities agree as to the inestimable value of opium in the treatment of all intestinal obstructions, but all are not agreed as to the wisdom of its exclusive use.

Purgatives. The authorities unite in opposing the use of purgatives. Concerning their use, Prof. Geo. H. B. Macleod¹ says, "When given early, in most instances purgatives only augment the already exaggerated peristalsis; and if administered late they have an exhausted and paralyzed bowel to deal with."

Sir Thomas Watson writes as follows: "Withhold purgatives in these cases, because they are not merely useless, but positively hurtful, — hurtful not only in the late but in the early stage of the obstructive process; not merely condemned by an experience which is sometimes equivocal, but contraindicated by whatever rational principles can be deduced from the physiology and pathology of the malady."

Enemata. The preponderance of authority is in favor of the use of enemata in conjunction with the opium treatment. Dr. Brinton says, "Enemata are another means of treatment of great importance. The water they introduce into the system is no contemptible aid to nutrition. And the substitution or admixture of milk or gruel confers on them a further contingent usefulness. But their chief value depends on the chance of their gradually distending the bowel at the obstruction, and releasing the impacted or intussuscepted part. The remedial effects of their warmth and moisture we need not discuss, but we may fairly presume its analogy to the known effects of external fomentations to inflamed parts." He is emphatic in

¹ British Medical and Surgical Journal, November 25, 1876.

the injunction that the administration of enemata should never be left to an ordinary nurse, but should be regarded as an important operation, only safe and efficient if undertaken by a person of competent skill.

Leichtenstern speaks approvingly of what he terms the "monster clyster" treatment in all forms of obstructions of the bowels, and says that by its aid we often reach diagnostic conclusions regarding the seat of obstruction. If the patient be brought fully under the influence of opium or chloroform, the ileo-cæcal sphincter can be relaxed so as to open the way for the injected water to reach the point of obstruction.

In connection with the "monster clyster" treatment, some of you will recall a paper on the subject of Intestinal Obstruction, by Dr. Robert Battey, published in the *Atlanta Medical Journal* in 1874, in which he strongly recommends very large enemata, as much as two and a half or even three gallons of water.

Mercury. The use of crude mercury, which was a favorite remedy in the past, is now very generally condemned. Brinton strongly urges its disuse, because he says it often does harm, embarrassing the bowel and increasing the distention and pressure, and predisposing to paralysis, inflammation, and gangrene.

Insufflation or inflation with air has been commended by writers on the subject from Hippocrates down to the present day, particularly in cases of intussusception. It acts in the same way as enemata of water by producing mechanical distention, but, according to Brinton, it is more sudden and violent and less manageable as a distensive agent than a liquid enema, which may easily be made to fill the whole large intestine without inflicting upon the patient any danger.

Gaseous distention from the action of an alkali upon an acid within the bowels is open to the objections just mentioned against insufflation of air.

Belladonna in small doses is inferior in its action to opium, and in large doses is more dangerous. Combined with opium, however, the most happy effects are often obtained in the arrest of pain and peristalsis of the bowels.

Calomel is objected to because it stimulates the peristaltic action of the bowel, when the first object should be to arrest the peristalsis.

Galvanism is of but little or no service except in cases of obstruction from simple fecal impaction.

SUMMARY OF IMPORTANT POINTS IN THE STANNARD CASE AS ESTABLISHED BY MEDICAL EVIDENCE.

BY C. T. PECKHAM, M. D.

THIS case excited an unusual degree of interest from the sensational character of the proceedings and the length of time — ninety-seven days — occupied by the State of Connecticut in prosecuting the defendant, the Rev. Mr. Hayden. The evidence was entirely circumstantial. The jury disagreed, standing eleven to one for the defendant.

As Professor Samuel Johnson testified that by chemical analysis he found 83.23 grains of arsenic in the stomach and liver of Mary E. Stannard there could be no doubt that she was poisoned, unless the poison was placed in the stomach after death. It is true that there were four exhumations, but the physi-

cians present say there was no opportunity for any one to place arsenic in the stomach. Furthermore, Drs. Jewett and White agreed that there was conclusive evidence of inflammation in Mary E. Stannard's stomach. Dr. William Hotchkiss proved by experiments on stomachs of people recently dead that arsenic in such stomachs produces no evidence of inflammation. Arsenic was found in the brain. According to Professor Thomas G. Wormley it would take arsenic thirty days to reach the brain by osmosis. The head was taken from the body within thirty days after death. It seems to have been clearly shown that arsenic in sufficient quantity to cause death was taken by Mary E. Stannard before her death.

The State claimed that Hayden bought arsenic in Middletown on the day of the homicide. The accused admitted the fact, and claimed that he put it in his barn. This arsenic, found in the place where Hayden said he put it, the State claimed was not the arsenic which Hayden purchased at Middletown on the day of the homicide, but was another quantity bought to replace that which he gave to Mary E. Stannard. It seemed important to prove that the arsenic in Mr. Hayden's barn was not like the arsenic kept for sale at the time of Mr. Hayden's purchase by Mr. Tyler, of Middletown, of whom Mr. Hayden admits that he bought arsenic on the day of the homicide.

To obtain this proof the State of Connecticut paid Professor Edward S. Dana's expenses to England to investigate the various processes by which arsenic is manufactured. As a result of his investigations he claimed that arsenic produced at different manufactories possessed different characteristics. If these different characteristics could be detected in any way, they could be detected by the microscope. Professor Dana said that he had examined arsenic obtained from many druggists, and that many samples were so dissimilar that if one hundred unmarked samples were placed before him he could instantly separate them into groups.

Connected with this case were four important samples, namely, from the barn, from Colgrove, from McKee, and from the stomach of the victim. The barn arsenic is that from Mr. Hayden's barn. The Colgrove sample was purchased of Mr. Tyler, druggist, who obtained his arsenic of McKee, of Middletown. Of the four above-mentioned samples Professor Dana said that one, the barn arsenic, was wholly unlike the other three. The Colgrove, stomach, and McKee specimens were so nearly alike that he believed they came from the same source. The differences between the arsenic from the barn and that from Colgrove may be thus tabulated:—

	Percentage of Crystals.	Size.	Surface.	Reflection.
Colgrove.	33½ to 50	.05 to .001 inch in diameter.	Uniformly rough.	Dull.
Barn.	50 to 75	.001 to .002 inch in diameter.	Uniformly smooth.	Brilliant.

The stomach arsenic differed from the McKee and Colgrove samples in only one respect. On the surfaces of the crystals of the former were parallel markings, meeting at the angle of union of the faces, like markings of the adjacent sides. Similar markings were produced on the McKee sample by placing some of the crystals in water. The testimonies of Professors Wormley and William H. Brewer agreed in the main with Professor Dana's. The product of crystallization, Professor Dana said, would be affected by

temperature and the rapidity of its change, by the density of the vapor and the amount of foreign matter in it, and by the presence or absence of a foreign surface to which particles might adhere to form crystals. In manufacturing arsenic the vapor passes through several chambers to be cooled and condensed. The product of one chamber often differs from that of another at the same sublimation. If the products of the different chambers were mixed, Professor Dana did not think the resulting product would vary from ninety-two per cent. of crystals to ninety per cent. of other objects. If ten samples came to him from the same source he could say they were similar; if from different sources he could say with perfect confidence that they were from different sources. He admitted that there was more difference between a sample of Tavistock arsenic sent him by Dr. Squibb and his sample from the Tavistock mill than between the barn and the Colgrove samples. The Garland arsenic, he said, contained more crystals than the Tavistock. Twenty or thirty minerals crystallize in the octahedral form. Sugar never so crystallizes.

The State claimed that Mary E. Stannard thought she was pregnant, and had convinced Hayden that she was. Medical evidence established the fact that she was menstruating at the time of her death. Dr. Jewett said that the small ovarian tumor, the size of a walnut, might produce the symptoms of pregnancy, especially if she were imprudent before their appearance. This evidence was wholly denied by Professor Stephen J. Hubbard, of Yale, who said that this tumor could not have produced the slightest symptoms of pregnancy, for there was no inflammation in or around the growth.

Dr. Treadwell did not find blood on the clothes worn by Hayden on the day of the homicide. He did find twenty corpuscles in the thumb groove of Hayden's pocket knife. These were $\frac{32}{32}$ of an inch in diameter on an average, and might have been human or dog's corpuscles. Hayden showed an old cicatrix on his finger, which he said resulted from a cut by the same blade on which the blood was found.

RECENT PROGRESS IN MATERIA MEDICA AND PHARMACY.¹

BY W. P. BOLLES, M. D.

Coto Bark (or Barks). — Messrs. Jobst and Hesse have contributed to *Liebig's Annalen* an elaborate article, which has been republished in part in the *Pharmaceutical Journal and Transactions*. According to these authors, there are two similar but distinct products imported under this name, the first of which they designate "genuine coto bark." It was obtained from Bolivia under the name of coto cinchona, although bearing no resemblance to cinchona.

As described by Hartz, it consists of irregular, flat, and slightly curved pieces about 0.6 m. long, 60 mm. broad, by 8 to 14 mm. thick. It is of a reddish cinnamon color, but somewhat darker on the inner side. As a rule it has the appearance of having had the outer layer intentionally removed. It has a pleasant cinnamon smell, but soon produces an irritating action upon the nostrils. The taste is pungent, but not bitter, expecto-

rant, nor astringent. It has a somewhat unequal texture, the outer portion forming a granular and tolerably evenly breaking mass, lying on a coarse fibrous and unevenly breaking cellular portion of which the inner part consists.

Shortly after the second kind made its appearance, said to have been collected from the shores of the river Mapiri, in Bolivia. It is in slightly larger pieces than the "genuine," having similar color and fracture. It had occasionally deep whitish furrows upon its surface. Its smell is less pungent, somewhat resembling nutmegs; its taste is milder. To distinguish this bark they named it "paracoto." Both kinds are sold indiscriminately in the market, under the name "coto bark." Their therapeutic qualities seem to be similar, although "paracoto" is the weaker of the two.

Genuine coto bark contains, as its most important ingredient, cotoin. This is obtained, in brief, by extraction with ether, separation by petroleum spirit, and subsequent purification by repeated crystallization from boiling water. It crystallizes both in prisms and plates; has a pale yellow color; is soluble in alcohol, chloroform, etc., somewhat so in boiling water, very slightly so in cold. It is easily dissolved by alkaline solutions, from which it may be precipitated by acids. It has a neutral reaction in aqueous solution and a bitter taste; its dust is sternutatory. Its formula appears to be $C_{22}H_{31}O_6$. Associated with the cotoin, and perhaps produced from it, is its anhydride, dicotoin, resembling the former in many respects.

In "paracoto" more numerous substances have been discovered: Paracotoin is obtained, together with several other crystalline substances, by extraction with ether and spontaneous crystallization. The mass is then dissolved in hot alcohol, and the paracotoin, separated by fractional crystallization, being first deposited. It is formed in beautiful pale yellow laminae, capable of fusion and sublimation; it is soluble in ether, chloroform, and boiling alcohol, and somewhat so in boiling water. Potassic and sodic hydrates dissolve it with decomposition, forming paracotonic acid, of which it seems to be the anhydride. It has no taste. Leucotoin is the chief constituent of paracoto; it is separated from the mother liquor of paracotoin by crystallization and resolution in glacial acetic acid, evaporation and subsequent crystallization from very dilute boiling alcohol. It is in the form of small white prisms, easily soluble in alcohol, ether, and chloroform, slightly so in boiling water, in which it melts; its solubility does not seem to be increased in alkaline solutions. Oxyleucotoin resembles leucotoin in its general properties; it is separated from crude paracotoin by dilute potash or soda which dissolve the latter and leave the oxyleucotoin behind. Dibenzolhydrocotoin crystallizes in striated white fusible prisms; is easily soluble in boiling alcohol and in chloroform, less so in ether and boiling water. Hydrocotoin has remained in the mother liquor, from which the other products have been separated, and piperonylic acid remains in the bark itself, after the above extraction by ether. In addition to these, "paracoto" furnishes a composite essential oil, to which its odor is due. As a rule, the commercial preparation termed cotoin consists of a mixture of crystalline products, such as could be obtained from paracoto bark, as described above, excepting the oil and acid. Coto bark is highly recommended for diarrheas. The most desirable preparations are cotoin and paracotoin, since the crude drug, or its tincture, acts unpleasantly upon the

stomach. Doses: cotoin, .01 to .05 gm., paracotoin, 0.1 to 0.2, every two or three hours; the other ingredients, oxylecotin, leucotin, and hydrocotoin, are much less active.

Cinchona Culture.—One of the most important enterprises connected with materia medica in the present generation has been the successful transplantation and cultivation of cinchona-trees in India, Java, and other places. The whole achievement, involving studies of climate, soil, elevation, species, to say nothing of the undertaking of carrying tender plants accustomed to high elevations over nearly the semi-circumference of the earth at the sea level, has been a triumph of what may be called horticultural engineering, and has been executed by very able hands. When the American Pharmaceutical Association met in this city, samples of the earliest exportations from the Indian plantations had just been received, and were on exhibition as curiosities. Since that time the Indian barks have constantly increased in quantity, and are now a regular item of British commerce. More than this, European intelligence has learned that the bark can be removed without destroying the tree, and successive crops be raised of constantly improving quality. Mr. David Howard, a nephew of the celebrated quinologist, J. C. Howard, who has been much interested in the subject, has written an interesting paper, of which the following is an abstract. The chief points of interest in the paper are the effects of the age of the tree and "renewing" upon the quality of the barks, and the comparative value of the outer and inner portions of the bark as bearing upon a proposed new mode of collecting without injury to the tree. The opportunity for the first study is given by the custom of sending barks from the government plantation at Dodabetta, with the date of the plantation from which each parcel was obtained, and also of separating the "natural," "mossed," and "renewed" samples. The specimens were from trees planted each year from 1863 to 1867. As the "natural bark" can be obtained from the lower stems but once, that from the older plantations coming under this head must be from the branches or from saplings and inferior trees, and for this reason it proved to be less valuable than the "natural" of the later plantations; but the "mossed" barks, or second crops, far from deteriorating, were best from the oldest, as Mr. Howard believes, from greater maturity. These specimens were from *C. officinalis*. Recent importations of *C. succinbra*, on the other hand, seem to show that the oldest trees have some of them passed their point of greatest percentage of alkaloid.

From a specimen received from Darjeeling of a bark accidentally renewed (the tree having been injured), and not covered or mossed at all, and which yielded 5.1 per cent. of alkaloids, he concludes that the importance of "mossing" depends upon its usefulness in protecting the tree, and not upon any effect in increasing the alkaloids.

An examination of the inner and outer portions of the bark of cinchona succinbra gave the following results:—

	Quinine.	Cinchonidine.	Cinchone.
Inner.	.5	1.2	1.4
Outer.	1.2	1.4	1.7

Thus not only is the total yield greater in the outer bark, but that of the quinine is greater in proportion. It is proposed by M. Moens to shave off this portion without cutting quite through the bark, and so do-

ing, practically, no injury to the growing tree, to enable it to produce a long succession of crops.

Cinchona Ledgeriana, a recently discovered species now cultivated in Java, has recently furnished bark of wonderful richness.

Araroba, Gon Powder.—Although this drug may be less important than it promised to be, still it is interesting to know that its botanical origin has been discovered and made known to the medical world by Dr. J. M. de Aquiar, of Bahia, in a monograph upon the subject. He has obtained flowers and leaves, which he has figured and carefully described, and believing it to be a new species has named it *Andira Araroba*. It is a large, straight-trunked tree, with a not very leafy spheroidal head and a thinish bark. It belongs in the great order Leguminosae, and has papilionaceous flowers and paripinnate leaves. The *Araroba* (that is, the drug) is found as a light-colored powder in lacunae in the wood more or less large according to the age of the tree, and is produced, as is supposed by the author, by oxidation of the abundant resin. It is collected throughout the year, the older trees being selected, cut, and split, and the powder scraped out of the cavities. The wood appears to be softened about these cavities. Lieberman and Siedler find that the chrysophanic acid does not exist in a free state in this drug, but as chrysarobin, which easily produces the other by oxidation. Chrysophanic acid is also found in other plants, as senna, docks, and rhubarb. An inferior variety of the latter has been suggested as a source of it.

Veratrum.—The veratrum have been the subject of a great deal of careful work both in this country and England; they contain a series of closely related alkaloids, separable with difficulty, and by no means yet well established. Messrs. Wright and Luff, who have spent much time upon them, as well as upon the aconites, have isolated no less than seven alkaloids, of which six, jervia, pseudojervia, rubijervia, veratralbia, veratria, ecardia, occur in our own *V. viride*. Mr. Bullock, of Philadelphia, who has paid much attention to this plant, substantially confirms their results; but obtains a much larger amount of the alkaloids, a result due, as he thinks, to separating them from the resin by saponifying the latter. The veratrum resin has always proved a great obstacle to the isolation of these bases. Despite these most careful researches, we are still in doubt as to the real cause of the recognized superiority of the American species over its so nearly related European congener album, which has caused it to replace the latter even in its own countries.

Ergot.—Ergot still gives pharmaceutical chemists work enough. Wenzell's ergotina and ecbolina were generally accepted as the active principles until Taurer, in 1878, isolated a crystallized alkaloid ergotinine (both the former were amorphous). Blumberg, from an extended examination of this drug, has come to the conclusion that the two alkaloids of Wenzell are the same. He also separated picrosclerotina, whose existence had been already indicated by Dragendorff, and found it to be very poisonous to frogs when fresh, but that it soon degenerates. He then experimented for Taurer's ergotinine after this chemist's method, but failed to obtain it; he afterwards did, however, separate some, and from experiments, both physiological and chemical, proved, as he believed, its identity. It, too, rapidly decomposed. Taurer, in a succeeding number, claims that Blumberg's "ergotina" can be only

a form of picrosclerotina, and claims that the former is not so unstable as the latter asserts. Sclerotic acid, another recently discovered substance, exists in ergot to the extent of four per cent., and is said to be very active. While thanking the gentlemen who are doing so much careful work upon this unstable drug, we think that physicians will do well to adhere pretty closely to a very fresh extract, or, better still, to the freshly powdered drug from the last crop.

Calabar Beans.—Occasional substitutions of the seeds of other leguminous plants for these have appeared in the market, but so different in appearance as to be easily distinguished. Recently, however, there have come among true calabar beans specimens which are longer, more cylindrical, and of a redder tint. These are now being examined by Mr. E. M. Holmes. Pods and leaves of the plant yielding them have been seen by this gentleman without discovering any essential difference between it and *Physostigma venenosum*, which yields the typical form; the flowers have not been obtained. From a rough test of the seeds he is led to believe that they are more active than the commoner variety. The name *Physostigma cylindrosperma* is offered for the plant.

Podophyllum had for many years the reputation of containing one or more alkaloids. Professor Mayer, in 1863, identified one of them as berberina. This seemed the more probable as this substance was known to be quite common in allied plants; but several observers since that time having failed to detect this or any other alkaloid in either the root or the resin, its absence has been for some time virtually conceded. Yet as it was known that some of its constituents were more abundant at one season than at another, it had been suggested that perhaps berberina was occasionally present. To settle this point, Mr. C. J. Biddle gathered the root at five different times from March to October, and after partially examining the specimens himself gave the "washings," or liquors in which the resins were precipitated and washed, to Professor Maisch for complete analysis as to alkaloids. Only the later samples gave even *prima facie* evidence of them; still Professor Maisch examined them all, and with the same result. There was not the slightest trace of the substances sought for, so that their absence at all times may now be taken as proved beyond doubt. It is not a matter of great importance, but it is a relief to have a long-disputed point settled.

Pomegranate-Root Bark.—Tauret, in 1878, isolated an active tannic acid alkaloid, which he named, in honor of Pelletier, pelletierina, an oleaginous, colorless, or slightly yellow, inflammable liquid. Its salts can be obtained crystalline, but are exceedingly hygroscopic. In continuing his examinations since that time he finds it to be associated with at least three other alkaloids: a left rotating one, found chiefly in the stem; a right rotating one, found chiefly in the root; and an (optically) inactive one. The first yields crystalline salts. Professor Falck objects to the name pelletierina as applied to any alkaloid from Punica, since there is a plant *Pelletiera verna*, with which the name will almost inevitably be confused.

—In the new Buffalo Homeopathic College it is announced officially that "during lectures, and amphitheatre clinics also, the female students are screened from the gentlemen, while they have the same advantages."

Hospital Practice and Clinical Memoranda.

A CASE OF LITHOLAPAXY.

BY E. F. SANGER, M. D., BANGOR,
Ex-President of the Maine Medical Association.

DURING the fall of 1879 I was called to Mr. B. N. T., aged sixty-four, with a catarrhal, asthmatic, and lymphatic diathesis. He had to give up business in May, 1877, and had been confined to his bed since January, 1879, with straining and constant desire to pass water every ten to thirty minutes, pain on change of position, and urine heavily loaded with pus and phosphates; pulse ranging from 90 to 100. Sound 22, French, detected a stone apparently at the base of the bladder, the impression being conveyed to the hand that the heel of the sound impinged on the stone.

He had lost sixty-five pounds of flesh. His age, condition, and the apparent magnitude of the stone augured ill for lithotomy or ordinary lithotripsy. Litholapaxy, or the rapid lithotripsy, seemed the only solution of my dilemma. By advice of Dr. Bigelow, I sent to New York for his evacuating apparatus and lithotrite.

Knowing Sir Henry Thompson's aversion to prolonged crushing, his want of confidence in the tolerance of the bladder, his opposition to evacuating tubes above 25 French, with some hesitation and delay I proceeded with the operation. Another discouraging feature was that the patient took ether poorly, the throat getting constantly clogged with mucus and the pulse running up to 120, and after three-fourths of an hour of etherization to 140 and 160. The above symptoms prevented us from testing the full tolerance of the bladder and a successful completion of the operation at a less number of sittings. It was therefore with some misgivings that I used the Bigelow lithotrite and the No. 29 French curved tube.

The operation proved full of difficulties. Forty minutes of continued search disclosed the stone back of or above the symphysis pubis, apparently fastened in a way that only the point of the sound or lithotrite could scrape over a fixed mass. I nipped away and evacuated thirty grains in the next twenty minutes. After this at short intervals there were two operations, the first lasting seventy minutes and evacuating ninety grains of stone; the second, one hundred and five minutes, with a product of one hundred and twenty grains. In both instances searching and crushing occupied two thirds of the time, and the handle of the lithotrite had to be carried back between the legs as far as it would go. At the last operation I succeeded in grasping a stone two inches in diameter, but not in detaching and breaking it up, as the lithotrite seemed to plow through it. As the patient had become very much exhausted, I evacuated rapidly and left some loose pieces in the bladder. I drew out one piece engaged in the eye of the tube, too big to come through the tube. The detritus occasioned high fever and cystitis, so that nothing more was done for three or four weeks. On one of these occasions I tried Ferguson's fenestrated lithotrite without engaging the stone, but several times seizing the mucous membrane, which was never done with the Bigelow instrument.

Between the third and fourth operations I met Dr. Bigelow in Boston, who expressed the belief that, the stone being large, and lying across the floor of the

bladder, the beak had passed under the centre of it. December 16th. I etherized the patient again, elevated the hips, and by forcibly depressing the handle of the lithotrite tilted it up, seized, crushed, and evacuated nine hundred and thirty grains of stone in seventy minutes. This time the lithotrite was introduced three times, occupying about half of the time. Very many pieces larger than peas were removed. Not daring to keep the patient any longer under ether, I left two or three pieces which I could hear click against the tube. December 22d. Crushed again, and evacuated in forty minutes sixty grains, one piece weighing twenty grains being extracted in the eye of the tube.

Thus in five and three quarters hours at five different operations twelve hundred grains were extracted, and at each time the patient suffered no detriment from the prolonged continuance of the instruments in the bladder, excepting the time when a considerable number of loose pieces were left unevacuated. I should have used the 31 French straight tube had not my greatest difficulty been in engaging the stone between the jaws of the instrument. The patient was on his feet in about ten days, and could hold water nearly all night. I have written a rather lengthy detail of the case because I consider it a most complete triumph of Bigelow's instruments under the most trying circumstances.

THREE CASES OF LITHOLAPAXY.

BY HAMPTON E. HILL, M. D., BIDDEFORD, MAINE.

CASE I. G. E., of Biddeford, aged twenty years, laborer. When I was called to see him he had been confined to the house about a year, with frequent micturition, followed by great pain, aggravated by exercise. Examination revealed a good-sized stone. Litholapaxy March 25, 1878; weight of stone, six hundred grains; composition, triple phosphate of lime and magnesia. Used Teevan's lithotrite; time two hours. The operation was followed by no inflammatory symptoms, and by rapid recovery. He has since been able to attend to his work as usual. A No. 27 evacuating canula was used in this case.

CASE II. J. M., of Saco, aged fifty-six, carpenter, had not been able to work for about three years; was considerably emaciated. Examination revealed a stricture in front of the bulb of the urethra admitting a No. 8 (French) bougie; after partially dilating the stricture the bladder was examined with a sound, and a stone found. Litholapaxy June 9, 1879. After giving the ether the stricture was dilated so as to admit the 27 (French) evacuating canula, and the stone was broken and removed. Weight, five hundred and twenty grains. Time occupied in the operation, one hour and thirty minutes. Composition of stone, triple phosphate of lime and magnesia. Bigelow's lithotrite was used in this operation, and proved to be much more rapid and thorough in its work than Teevan's, which was used in the first case. This patient had no inflammatory symptoms following the operation, and was allowed to leave his room in ten days.

CASE III. C. L. H., of Mercer, Somerset County, Maine, age twenty-five years, cabinet-maker. Had trouble with bladder for about four years. The last eight months of this time he was not able to work, and had frequent and severe attacks of hæmorrhage from the

bladder. Dr. John Robbins, Jr., of South Norridgewood, was called; examined bladder with sound, and found it contained a stone, but with the patient's condition did not consider the chances good for recovery if lithotomy were resorted to, and referred the case to Dr. H. H. Hill, of Augusta, Maine, by whose advice he wrote to me in regard to the case, and litholapaxy as a mode of relief. I saw the patient with Dr. Robbins, and performed litholapaxy September 16, 1879. No. 30 (French) evacuating canula was used, and Bigelow's lithotrite. Time occupied in operation, one hour and thirty minutes. Weight of stone that was saved, six hundred grains (some of the stone was accidentally thrown away, perhaps sixty grains). I stayed with the patient until the next day, when the pulse was 76; temperature normal. Dr. Robbins wrote me that two days after he had profuse hæmorrhage, and about five days later another attack, but recovered rapidly, and in about three weeks was able to be about comfortably, and finally, to return to his work. Composition of stone triple phosphate lime and magnesia.

Reports of Societies.

PROCEEDINGS OF THE CINCINNATI MEDICAL SOCIETY.

WILLIAM H. TAYLOR, M. D., PRESIDENT. WILLIAM JUDKINS, M. D., SECRETARY.

JANUARY 13th. DR. WILLIAM B. DAVIS read a paper on

INTESTINAL OBSTRUCTION,

which is published on page 193.

DR. BRECHL asked if any of the members had had experience with crude mercury. — DR. CARSON, when a student, saw his preceptor administer quicksilver without any beneficial results. The patient died. He had treated two cases of occlusion, with fecal vomiting, with opium in large doses, and both recovered. He thought well of warm-water enemata in early stages, but would give in addition full doses of opium. — DR. STANTON treated one case successfully during the late war with opium alone. He thought that great harm was often done in these cases by purgatives. — DR. WENNING. Case VI. of Dr. Davis was undoubtedly saved by the warm-water enemata. He considered it necessary for the physician to use the syringe himself, and throw the water high up by means of a large-size gum catheter. — DR. C. P. JUDKINS treated a lady for fecal impaction with large enemata of warm water. Impaction gave way, and the patient discharged immense quantities of strawberry seeds, and made a good recovery. He had thought that strawberries were laxative in their influence. — DR. DAVIS. Case V. was one of impaction from strawberry seeds. Dr. Carver, the attending physician, whose practice extends over a section of the country where strawberries are extensively cultivated for the market, informed him that he had treated six cases of impaction from strawberry seeds. — DR. COMEYERS said that he had met with four cases of intestinal obstruction during the past four years, in each of which the patients were apparently relieved by very large injections of tepid water, repeated as often as needed. At the same time opium and morphia were used, the latter hypodermically. Three of the cases were consultations; the fourth was his own patient, with regard to whom he made at the time

the following brief note: Morris B., aged thirty-three, an attorney, general health good, was taken with general bad feeling, accompanied with slight fever, on Friday evening, May 19, 1877. He thought it all due to improper food. I saw him next morning, 20th, and found him with some tenderness in right iliac fossa, and a temperature of 101.5° F. I ordered a mild purgative. At my evening visit found that the bowels had not been moved and the local pain was increased. I suspected typhilitis, and prescribed six leeches for the region of pain, and small, repeated doses of calomel and jalap. May 21st. On my call found that the medicine had not acted and the pain was not alleviated. Ordered castor-oil and turpentine diffused in a pint of water as an enema. No action of the bowels following, I concluded that I had to deal with an obstruction of the intestinal tract. I now gave one third of a grain of morphia hypodermically, and injected the bowel with as much tepid water as he could bear, — between two and three quarts. This was repeated twice, also the morphia, during the night. All distress of the patient had subsided under the use of the morphia. On the next morning (22d) I began the use of castor-oil, tablespoonful every forty-five minutes for three doses. There were some fecal discharges during the day, accompanied by gas. On the 23d I gave him another large injection, which was followed in due time by an abundant fecal evacuation. It was quite a week before he could resume his office duties. I think that the physician should always administer the injections. I have great confidence in the use of huge injections of tepid water. Of course there are obstructions in which they could bring no relief. — Dr. CANSON said: The subject of intestinal obstruction is always practical and interesting. Notwithstanding the variety of causes, the modern treatment of it is comparatively simple. In some previous remarks he had illustrated the treatment of cases by the use of opium or hypodermic injections. In the present discussion very little had been said about the surgical treatment, and yet it has been of late attracting a good deal of attention, as reference to hospital reports, society proceedings, etc., will show. I shall refer to two cases, the review of one of which and the history of the other as reported will serve to introduce the question of surgical interference. My own experience is too small to be of any interest, as I never saw the operation but once, and it was fatal. The case to which I referred as coming within my observation was a woman about forty years of age, whose general history of good health had never been disturbed much except by a number of confinements. Near five years ago there began the symptoms which, at several different periods up to the time of her death, had recurred with the same general features of fecal impaction and pain, with relief by opiates and laxatives. There was evidence, satisfactory because she was under intelligent observation all the time, that the tumor-like mass had never entirely disappeared. The fear of malignant growth had been present in the minds of her physicians after her later attacks, as the mass was large, irregular, and quite indurated, and yet the duration of the case argued strongly against the view. The last attack, during which she died, was one of severe pain, less of tumor enlargement, nausea, fecal vomiting, and distention, with no satisfactory action of the bowels after several cautious attempts with laxatives. The treatment was principally the opiate-and-enemata plan,

A post mortem showed no peritonitis, great distention of the small bowels above a point about five feet above the ileo-cæcal valve. At that point there was felt an obstructing mass lying on the left side of the abdomen, whereas all of the previous impactions were located in the region and direction of the ascending colon. On section through the bowel at the point of the obstructing mass (which allowed nothing to pass) there was removed a body about one and three quarters by two and one half inches in measurement, with the color and general external appearance of a very large gall-stone. What the more minute examination of its structure has since shown I do not know, as I have not seen her physician since. There were evidences that the concretion had passed by ulcerative action from the gall-bladder directly into the duodenum, as there were adhesions between the bowel and gall-bladder, and also a cicatrix on the mucous membrane of the duodenum, though nothing in her history could have suggested the probability of such a thing.

In the last (the twelfth) volume of the Clinical Society's Transactions is related a case parallel in several respects with this one, especially as to the cause of obstruction and the probable mode of entrance of the concretion into the bowel. Mr. Bryant concluded to operate: he found the concretion, a gall-stone that weighed two hundred and thirty-eight grains, and measured one and seven eighths by one and one eighth inches, and three and one quarter inches in circumference. His case was more unpromising than the one we relate, because of peritonitis. There was reason, however, to attribute our case to some cause several years in action, and it did not therefore come so clearly within Mr. Bryant's emphatic dictum, which he lays down in the following language: "I hold that in all cases of acute intestinal obstruction that resist medical treatment operative relief should be resorted to as soon as a reasonable diagnosis has been made, and that, as in a desperate case of strangulated external hernia, an exploratory operation should be performed in most cases. I believe that the physician or surgeon has no right to waste time whilst he is speculating as to the exact seat of the obstruction or precise cause by which it has been brought about, since there is no room to doubt that during this ruminating process the prospects of recovery are rapidly diminishing. Indeed, I believe a surgeon may as well delay in cutting the rope in a case of suicide by hanging whilst he is speculating as to the influences which have led the man to perpetrate the act as to delay operative interference in a case of acute intestinal obstruction with the hope that he will be able to make a scientific diagnosis of the case, or that something will turn up by which relief may be obtained." "I maintain that it is not required of the surgeon to *diagnose the precise cause of the obstruction so long as the diagnosis of its existence can be determined*; and do not think because such cases as these occasionally recover without operative treatment we should forget that a large majority die miserably, unrelieved. I plead, therefore, for the majority." Many of us have felt just such helplessness as Mr. Bryant here records in the presence of such cases, and I have felt that perhaps we have not given as much weight to such language as Mr. Bryant uses as the facts required. The application of his rule to our case would have given the patient a better chance than persistence in the course which we pursued. I repeat that the surgical treatment

of obstruction seems to be more prominent, and deserves consideration in this discussion. — DR. DAVIS. The difficulty of determining the cause and locality of the occlusion is a great stumbling-block in the way of surgical interference. An old writer has said that in intestinal obstruction we cannot accept any diagnosis not certified by a post-mortem examination. Brinton does not think gastrotony justifiable, while equally weighty authorities advise it under certain restrictions, believing that it gives the patient one more chance. The introduction of a fine trocar into the distended intestine gives great relief by allowing a discharge of the gas. This operation may be done repeatedly if the trocar is properly disinfected. Larger trocars have been thrust into the non-resonant parts of the abdomen for the removal of the liquid feces above the obstruction. — DR. N. P. DANDRIDGE. In the discussion of a subject like obstruction of the bowels there is always difficulty in making comprehensive and general statements, from the fact that the conditions under which obstruction exists are so entirely different in different cases. This difficulty is especially apparent in the discussion of any plan of treatment which shall be generally applicable where obstruction is the prominent symptom to be overcome. The variety of conditions under which these cases occur is well illustrated by Dr. Davis's paper. Examples of peritonitis, invagination, twist, and impaction were all presented in the six cases reported. The diagnosis in individual cases of the exact seat and cause of the trouble is notoriously a most difficult and often an impossible task. It is this difficulty in diagnosis of the essential condition present that makes it impossible to advocate with confidence any routine course as suitable to all cases. Each individual case must be considered for itself, and a correct diagnosis must precede a judicious treatment. Two general rules, however, seem to be applicable to all of these cases, — first, the full and free use of opium to allay pain and to secure complete rest to the bowels, and, secondly, the contraindication to the use of active purgatives by the mouth. These two factors in the treatment naturally supplement one another. As for the use of injections into the bowels, their effect must depend upon the situation and character of the obstruction. In general terms it may be stated that where the obstruction is above the ileo-cæcal valve injections are not likely to be directly efficient; not that the emptying the lower bowel may not prove beneficial, but in such conditions as impacted gall-stones, twists, invagination, or incarceration from old adhesions, relief or any effect whatever from injections must be regarded as fortuitous, and not to be relied upon. Even where the obstruction exists low down in the large intestines, injections may only aggravate the trouble. Of this I saw a notable example in the mortuary of the Cincinnati Hospital some time ago, in the case of a woman suffering from obstruction, where large injections of water had been thrown up the bowel and been retained. At the autopsy, a twist in the sigmoid flexure was found to exist, giving rise to a valve-like arrangement which permitted the injected fluid to pass up the bowel, but prevented its return. The sigmoid flexure was enormously distended with water, and filled a large part of the abdominal cavity.

In this connection I may mention two autopsies which I have recently seen. In one, a case of acute onset, which ran its course in a week, a section of the upper part of the ileum twenty inches long was found, of

a dark mahogany color, somewhat softened, and its vitality completely compromised. There was entire absence of peritonitis, no twists or bands, and absolutely nothing which would explain the manner in which the circulation had been cut off. The only explanation given was the probable existence of a twist completely compressing the vessels of the involved mesentery, which had become untwisted, possibly by some accidental movement, before death. In another case a loop of intestine had slipped under an old adhesion and become incarcerated. In neither of these cases would an injection have proved of the slightest value in overcoming the especial lesion present.

DR. DAVIS. Dr. Dandridge takes the position that enemata can be of no service except for emptying the lower bowel, when the occlusion is above the ileo-cæcal valve. Leichtenstern distinctly states that the ileo-cæcal valve can be so relaxed by large doses of opium or chloroform as to open the way for injected water to reach the point of occlusion, and he particularly mentions twist, knot, and invagination as conditions of obstruction where enemata will be most serviceable. Brinton, either directly or indirectly, expresses the same views.

DR. GOODE gave the particulars of a case to which he had been called in consultation in which the obstruction had existed for three days. There were constipation, fecal vomiting, and intense pain below the umbilicus. Opium treatment was resorted to, morphia being given hypodermically in doses of two thirds of a grain as often as the necessities of the case demanded. No point of induration or tumor could be discovered, on account of the extreme pain, tympanites, and the fact that the inflamed portion of the intestine was partly in the pelvic cavity.

On post-mortem examination he found invagination of four or five inches of the ileum. The peritoneum was much inflamed, and the invaginated portion of the intestine sphacelated. In this case surgical procedure might have relieved the invagination if resorted to early.

THE ANNUAL MEETING OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.

The annual meeting of the New York State Medical Society was held in the Geological Hall at Albany, on the 3d, 4th, and 5th of February. There were more than two hundred members in attendance. The proceedings were interesting and profitable, and the session was altogether a very agreeable one. Among the resolutions passed was one by Dr. John C. Dalton, securing the appointment of a special committee to act at such time and in such manner upon the question of vivisection as in their own judgment they should see fit; and one by Dr. Abram Jacobi, to the effect that the president should appoint a committee of five members to cooperate with the Society for the Prevention of Cruelty to Children in measures looking to the physical and moral welfare of young children. The latter resolution was offered with special reference to the recent disclosures of mismanagement and cruelty at the Shepherd's Fold in New York, and the committee thus appointed was instructed to report at the next meeting of the society.

THE PRESIDENT'S ADDRESS.

The annual address was delivered by the president, Dr. H. D. Didama, of Syracuse, in the Assembly cham-

ber of the new Capitol, on Wednesday evening, February 4th, and was listened to by a large audience of ladies and gentlemen. Dr. Didama, after dwelling for some time upon the advance which had been made in the last few years in various departments of medicine and surgery, and especially in regard to ovariectomy, alluded to the vast work that yet remained to be done in discovering the methods of successfully combating many forms of disease that still baffled all our skill, and spoke of the good which might be accomplished by an efficient state board of health in instructing both the laity and the profession about ventilation, drainage, sewerage, and other points of hygiene; in teaching, and practically demonstrating as far as possible, that the zymotic diseases are preventable and ought to be altogether abolished; and in impressing upon the minds of the people the conviction that the continuance of these diseases implied not only ignorance, but criminal negligence. In treating of the discouragements and difficulties which lay in the way of the advancement of science, he touched upon the well-meant but ill-advised opposition to vivisection that had to be contended against, the general lack of physiological and sanitary knowledge among the public, and the insufficient and faulty training which students of medicine, as a rule, received. In concluding, however, he expressed confidence in the realization in the future of all the hopes of the enlightened physician of the present day; saying that, however anxious he might be that needful reforms should take place speedily, he was not discouraged at the slow progress which faithful truth made in permeating the masses of men; nor was he doubtful of that final triumph of sanitary, medical, and moral science, when "there shall be no more an infant of days, for the child shall die an hundred years old."

At the close of the address the annual banquet was held at the Delavan House, and among the toasts were the following: "The later advances in special medicine a natural development of the universality of scientific inquiry," responded to by Dr. D. B. St. John Roosa; "The medical profession in England. The names of its great teachers are high in the list of those who have advanced the science of healing," responded to by Dr. Lewis A. Sayre; "The autocracy of the protoplasm in connection with the spontaneity of generation," responded to by Dr. John C. Dalton; "The government of the State. May it know its duty to the health, wealth, and happiness of the people," responded to by Dr. William C. Wey, of Elmira; and "The younger members of the profession," responded to by the veteran, Dr. Frank H. Hamilton.

The annual

ELECTION OF OFFICERS

took place on the morning of the 5th, just before the final adjournment, and the following is a list of the principal ones chosen: president, Dr. Wm. H. Bailey, of Albany; vice-president, Dr. Abram Jacobi, of New York; secretary, Dr. William H. Smith, of Manlius; treasurer, Dr. Charles H. Porter, of Albany; censors, Drs. Gouley, Agnew, Ferguson, Barton, Cooper, Churchill, Walcott, Chamberlayne, Wyckoff, Rochester, and Lapp; permanent members from New York, Drs. Piffard, Weir, and H. Knapp; delegate to the Massachusetts State Medical Society, Dr. Albert Vanderveer, of Albany; honorary members, Dr. J. S. Billings, U. S. A., Dr. Joseph B. Brown, U. S. A., and

W. F. Teevan, F. R. C. S., London; delegates to the American Medical Association from New York, Drs. Roosa, Gouley, and Hulton.

Other business transacted during the session was the making of a change in the by-laws which increases the annual dues of permanent members from two to five dollars, and the appointment of a committee, with Dr. H. G. Piffard as its chairman, to investigate some proposed revised statutes in reference to the practice of medicine in the State. Dr. Diamond, of Cayuga, in presenting a number of names for inscription upon the roll of honor, which is designed to contain the names of physicians who have rendered some specially valuable service to the cause of medical science, recommended, in the form of a motion (which was carried), that the names of those who have made useful discoveries or inventions in surgery should be included.

Among the papers of practical interest was one by Dr. John P. Gray, superintendent of the New York State Lunatic Asylum, on

THE USE OF HYOSCYAMIA IN INSANITY.

Dr. Gray gave briefly the results of the experience at the above institution in the use of the drug. He stated that it had been the practice at the asylum, from time to time, to make a study of special remedies "to determine as far as possible their therapeutic value and their application to the conditions of the insane." Of the action of hyoscyamia he said: "In cases of acute mania and melancholia with frenzy, no remedy we have used has so efficiently and readily calmed the high nervous and unsequal excitement, and brought about a degree of tranquillity essential to acquiescence in nourishment and rest, as a means of restoration." It was also found of great value in controlling the cerebral excitement of certain cases where there was persistent refusal of food, as it made it "reasonably easy and entirely safe to introduce the stomach-tube and administer the necessary food."

Several cases were then reported in order to illustrate the uses of the drug, after which some general remarks were made concerning its effects upon the circulation and the cerebral nerve tissue. The writer says: "As a general rule in these cases, it is not necessary to continue the remedy for any length of time; indeed, it is quite sufficient to give it once or twice a day (or once during the day and once at night) for a few days, and then intermit its employment. One might say, to see a patient while moderately under its influence so much more comfortable, that it simply breaks up these habits of restlessness, tearing, etc. Perhaps this is sufficient explanation; but I am inclined to think that it produces an effect upon the cerebral nerve tissue of a beneficial character, quieting the irritable and excited brain quite as markedly as preparations of opium, in their influence on nerve tissue, will relieve pain. At all events, we have found it very useful as a medicine, and that, discriminately used, it aids in the comfort and restoration of the patient; while in no instance has it proved harmful. To be able to give even a reasonable brain quiet in conditions of frenzy is quite as comforting and aidful as to relieve the restlessness of a fever patient by a bath, and saves from just so much unnecessary wear and tear. I have found it beneficial in cases of hysteria and also in chorea."

The crystallized hyoscyamia has been used, and also

the crude fluid form; the former in doses varying from one eighth to one half a grain, and the latter in doses reaching a grain. In simple restlessness from cerebral irritability and in certain hysterical affections one sixtieth to one thirtieth of a grain of the crystallized drug was prescribed with much benefit. It has also been used in connection with morphia—in pill form—after the following formula:—

R Morphine bromidi	gr. iv.
Ext. nucis vom.	
Papierin	aa gr. viij.
Hyoscyamine (cryst.)	gr. iij.
Ft. pil. No. xxx.	

One of the most important papers was that presented by Dr. James R. Leaming, of New York, its subject being

ENDEMIC PLEURO-PNEUMONIA, AS SEEN IN NEW YORK DURING THE PAST TEN OR TWELVE YEARS.

This affection, the writer states, has had distinct and peculiar factors during the period mentioned, some of which were known, while others were unrecognized or obscure. For many years a form of fatal pleuro-pneumonia has prevailed in the cities of the Southern States, and there has been a gradual procession of this form Northward, which reached New York about the year 1868. Statistics are then given to show to what extent it has influenced the bills of mortality since that time. Many of the cases ran so rapidly towards a fatal termination that curative measures were useless, before the gravity of the case was comprehended. The disease had assumed a new phase, new factors having been added to its causation, which required diligent investigation in order that it might be successfully combated. Dr. Leaming then alludes to an epidemic of pleuro-pneumonia which had its origin in Canada during the war of 1812-15, and contends that, though it may not be possible to prove that endemic pleuro-pneumonia as it is known in New York is the legitimate successor of the contagious typhoid pneumonia of that period, there is certainly more than a probable connection between the two. When the fatal forms of pneumonia began to occur, ten or twelve years ago, he, in common with other physicians, was surprised at the failure of the simple treatment which had up to that time answered perfectly well in the disease, and became impressed with the fact that with the change of type there had also been changes in the pathological process. The cases were more "typhoid" or of depressed vitality, and the intrapleural complications more frequent and of grave import. Indeed, the increase of mortality was measured by these complications.

Hence, some method of treatment more efficient was necessary. The late Dr. George P. Cammann had taught that in cases of great and sudden congestion of the lungs—the very conditions which are now recognized as indications of interpleural complication and rapid plastic exudation—very large doses of calomel, used promptly, would control the disease and prevent a fatal termination. The inefficiency of the expectant method rendered a resort to the heroic a necessity, and it was attended with very encouraging results. Cases such as had proved fatal under the mild measures previously employed were saved by the prompt exhibition of sedative doses of calomel, which are less depressing to the system than smaller doses repeated. With the immense prejudice operating

against the use of the remedy, however, it requires the courage of experience to give the very large doses that are required,—twenty, thirty, forty, or even sixty grains.—and it is safer to give a few grains more than might barely suffice than to repeat the dose. After quoting Dr. Graves's authority for the free use of mercury in dangerous cases, the writer goes on to say that the best way of giving calomel is to put it on the tongue and leave it there. Its rapid effect, he says, shows that it is influential before entering into the circulation, for it frequently has a sensible effect in controlling the heart's action and in reducing the temperature directly, while its full beneficial effects may not be had in twenty-four hours. It also acts more efficiently than anodynes in securing quiet and sleep; and another result of its use in these large doses, as noted by Dr. Graves, is that when internal inflammation is rapidly overcome, temperature and pulse falling with subsidence of all the alarming conditions, we may confidently expect the reparative process to continue until all is cleared up, and not a vestige of the disease remains. The safety of the large dose in any case where it is indicated at all is absolute; consequently, the physician, arriving at the conclusion that the sedative dose must be given, should not fail in courage to complete the work, so necessary to be done, by any half-way measures. Dr. Leaming next gives the interesting history of an attack of typical endemic pleuro-pneumonia, such as is now met with in New York, which occurred in his own person, and in which the happy effects of large doses of calomel were admirably shown, the temperature becoming normal on the seventh day. At its conclusion he puts the question whether the result would have been the same if calomel had not been used, and goes on to say, "I think not, and for these reasons: In the first place, none of the competent persons who saw the patient believe he could have lived until the seventh day had the calomel not been given; and, secondly, experience shows that where there is a large amount of plastic exudation defervescence does not take place on the seventh day, but the fever continues indefinitely.

But this heroic treatment should not be resorted to in every case. Notwithstanding the fact that endemic pleuro-pneumonia is fatal in its tendencies, other cases occur at the same time which are of the mild type, and in which the tendency is to get well; so that in these mild treatment only should be used. The lighter forms of the disease are to be distinguished from the more serious, first, by the rational signs, and, second, by the physical signs. In the mild form the respiration is not greatly oppressed, and although the febrile conditions, pulse, temperature, etc., may denote much activity, yet from the fifth to the ninth day there is sudden and generally complete defervescence with or without treatment, and the convalescence is uninterrupted; while in the most serious form there is dyspnoea from the beginning, lividity of the countenance, restlessness, and seeking of the upright position. The pulse is frequent and feeble, the skin cool and moist, and the temperature may either run very high or be moderate. In many instances the patient dies before the fifth day, and in those cases which survive a week or more there is no natural period of defervescence. The differences in the physical signs are equally marked. In the mild form the pneumonic conditions, sputa, etc., are sometimes well pronounced for days

before the physical signs of crepitant râle and bronchial breathing appear; while the crepitant râle is distinct, and not mingled with sub-crepitant or larger râles until the râle *redux* commences. In the severe variety, on the other hand, the râles are generally abundant and mixed, and begin with the disease, while the movement of the lungs is notably restrained. There is always marked flatness on percussion, also; and all these differences of physical signs depend upon the intrapleural complications. In the fatal cases there is a large amount of plastic exudation, generally in both pleuræ, and frequently covering the greater part of both lungs. In the one form the pneumonitis is the principal lesion; in the other the intrapleural plastic exudation.

Dr. Leaming has long endeavored to show that there has been a misconception of the significance of râles as a physical sign; contending that they are not intrapulmonary or intrabronchial, as a rule, but intrapleural—the exceptions being in larger mucous râles, which are generally intermittent or gurgling, when formed within cavities or in dilated bronchi. The grave cases have no regular course, except that their tendency is to a fatal termination; the hyperplasia of the blood being their distinguishing characteristic. Exudation of plastic matter into the natural cavities through serous membrane may take place, or the patient's life, perhaps, be brought to a hurried end, by the formation of a heart clot. The fullness of the heart's action and quickening pulse, the dusky ashen hue, the cold, clammy skin, and the spasmodic respiration, all show that death is commencing at the heart. The writer has frequently demonstrated to his own satisfaction the immediate connection between these signs and symptoms of disease and the plastic pathology of the blood and its exudation into serous cavities, with formation into clots in the heart and great blood-vessels. But others, he says, have not been so completely convinced as to the direct interpretation of the physical signs as applied to intrapleural processes, on account, perhaps, of the time elapsing after the diagnosis had been made until its verification after death. In the month of August last, however, he had an opportunity of obtaining proof, which he believes the most skeptical must acknowledge to be convincing. Through the kindness of Dr. J. D. Hopkins, veterinary surgeon of the commission appointed by the United States government for the purpose of stamping out contagious pleuro-pneumonia among cattle, he was invited to be present at the destruction of cows condemned by the commission, in order to examine them upon death by auscultation and percussion, and make diagnoses, which were to be immediately tested by post-mortem examination. The details of these cases are of great interest, but cannot be given here for lack of space. In all of them Dr. Leaming says the proof was complete. The râles always indicated adhesions, and when there were no adhesions there were no râles. He concludes the paper as follows: "Accepting, then, the evidence of râles as proof of intrapleural plastic exudation, we are unable to treat these cases in a manner commensurate with their gravity, and at the initial stage, when success is best attainable. . . . If prompt and energetic measures are to be decided upon, no time should be lost in putting them in force, that heavy blows may be given at the beginning, not to be repeated when the patient's strength is well-nigh exhausted. Everything afterwards should be support and

building up, and mostly by assimilable food, of which milk is the type."

(To be concluded.)

THE WHITE MOUNTAIN MEDICAL SOCIETY.

The White Mountain Medical Society met at Wells River, Vt., Wednesday, January 28th, Vice-President Adams, of Island Pond, in the chair. The forenoon session was occupied by a discussion on diphtheria, Dr. Moody, of Franconia, giving a history of the fatal epidemic in his town. In the afternoon there was further discussion of diphtheria, examination of patients, report of cases by Dr. Brown, of Wells River, and the exhibition of a specimen of peculiar fracture of the neck of the femur with dislocation, by Dr. Mitchell, of Lancaster. The evening session, which was a very interesting one, was opened by an able paper upon Abscess of the Spleen, by Dr. Mitchell, which elicited remarks from Prof. C. P. Frost, Drs. C. H. Boynton, Adams, and others upon similar experiences.

The election of officers resulted in the choice of Dr. C. G. Adams, Island Pond, Vt., president; Dr. C. P. Frost, Hanover, N. H., vice-president; Dr. C. R. Gibson, Woodsville, N. H., secretary; with the usual number of directors, censors, and delegates to local and general medical societies.

Thursday morning the members met at nine o'clock, and after a profitable discussion of two hours, in which the treatment of fissure in ano, and its accompanying diathesis, and treatment of varicose ulcers of the leg were thoroughly and profitably discussed, the society adjourned to meet at Thayer's Hotel, Littleton, N. H., in July next.

Recent Literature.

Atlas of Histology. By E. KLEIN, M. D., F. R. S., and E. NOBLE SMITH, M. R. C. S. Part IX. Philadelphia: J. B. Lippincott & Co. London: Smith, Elder & Co. 1879.

This is a number of perhaps double the usual size. Some of the subjects are among those in which Dr. Klein is particularly interested, and to researches in which he is largely indebted for his well-deserved reputation. The thymus is taken first, and quickly disposed of. Then comes a long and very valuable chapter on the lymphatics. We have a good account alike of the lymphatic trunks and the finest lymph spaces. Special attention is given, as might be expected, to the lymphatics of serous membranes. Klein describes at length the arrangement of the lymphatics of the diaphragm, and makes some remarks on their physiology, which we hope the readers of the *JOURNAL* will thank us for quoting:—

"The current passing through the lymphatics of the diaphragm is, then, from the free peritoneal surface of the diaphragm, that is, the peritoneal cavity, through the stomata vera into the superficial or radiating straight lymphatic capillaries, hence into the deep or circular straight ones; hence the current may pass in two directions, namely (a), into the plexus of lymphatic vessels forming the anterior system, and (b) into that of the posterior system; through the efferent trunks of the former the current passes a long and circuitous way (along the sternum) into a lym-

phatic gland, whereas through the efferent trunks of the latter it reaches in a short and unimpeded manner directly the thoracic duct. . . . The respiratory action of the diaphragm is the principal moving cause of the circulation of the lymphatics of the latter (Ludwig and Schweigger-Seidel), thus: during inspiration the straight lymphatics (both the superficial and deep ones) become distended, owing to the descent of the central tendon, and consequently the greater separation of its bundles from one another, while at the same time the pleural lymphatics become compressed; in this distended state of the superficial straight lymphatic capillaries the above stomata necessarily are wide open, and there exists therefore a tendency on the part of the straight lymphatic capillaries to absorb plasma cells or other formed matter that happens to be present on the peritoneal surface of the diaphragm. But at the same time, owing to the compression of the pleural lymphatics, these will discharge their contents into the efferent trunks. During expiration the straight lymphatics become compressed, owing to the tendon bundles becoming again closer, the pleural lymphatics being at the same time distended, for during the ascent of the central tendon the area of its pleural surface becomes enlarged. Hence the effect of the movement of the diaphragm in inspiration is the reverse from that in expiration, since during the latter the straight lymphatic capillaries become compressed, and therefore discharge their contents; these are readily received by the pleural lymphatics distended during this period." A similar suction action occurs also in the intercostal pleura.

The authors take up next the digestive system. The chapter on the teeth is, we are glad to say, devoted largely to development. The salivary glands, the tongue, œsophagus, and stomach are then discussed. The description of the peptic glands in the last-named organ is clear concerning points often obscure, but we confess to some doubt whether the so-called peptic cells never reach the central canal of the tube. The pyloric glands are said to be identical in structure with Brunner's glands, and we are promised more concerning them later. It is definitely stated, however, that they are not mucous glands, as has generally been believed. T. D.

How to Work with the Microscope. By LIONEL S. BEALE, F. R. S. Fifth Edition. London: Harrison, Pall Mall. Philadelphia: Lindsay & Blakiston. 1880.

The fifth edition of this work is before us, revised, enlarged, and enriched with many additional illustrations. It is somewhat difficult to define the scope of the book, which is larger than the name would imply. It tells us not only how to work with the microscope, but contains much information concerning the instrument itself, the principles involved in the construction of lenses, etc. Beside this we are given a glance at the structure of very many objects belonging to the animal, vegetable, and mineral kingdoms. A great deal of space is devoted to the application of photography to the microscope. Beside the technical part there is more or less concerning biology, and some rather sharp attacks on the materialist. We were about to say that the book might be called an encyclopædia; but that would be saying too much. The researches of what we may call the modern continental school, represented

by Cohnheim, Stricker, Ranvier, Klein, and others, are almost utterly ignored. Indeed, the names of the three latter observers are not to be found in the index. It would be better to say that the work is an encyclopædia of the Beale school of microscopy. This is not the school that we now follow in medical colleges, but there is much that is good in it. Mr. Beale's views of bio-plasm and formed material are very generally accepted, or at least respected. He certainly has shown great skill in making preparations. Those of us who work on different principles cannot afford to turn a deaf ear to Mr. Beale's instruction concerning many points. The book is handsomely printed, and the illustrations are very fine. T. D.

Annals of the Anatomical and Surgical Society. Volume I., 1878-9. Brooklyn, New York, 1879.

This volume contains the proceedings of a body of medical gentlemen, living in Brooklyn, interested in anatomy, surgery, and pathology, who have formed a society and a school for the purpose of advancing the study of these branches. The school, we are glad to learn, is not at all an addition to medical colleges, already too numerous, but is intended especially for advanced studies in the sciences mentioned. The plan seems an excellent one, and we wish it success. We have not space to review the papers read at the meetings during the past year. Suffice it to say that as far as we have examined them they promise well for the future usefulness of the society.

Brain-Work and Overwork. By H. C. WOOD, M. D., Clinical Professor of Nervous Diseases, in the University of Pennsylvania, etc. Philadelphia: Lindsay, Blakiston & Co. 1880.

This is No. X. of a series of American Health Primers, written by different specialists, and published by the same firm. Its subject is first of all in importance, and has been judiciously and ably treated by Dr. Wood. The style is pleasing, and the method simple, but revealing a basis of sound scientific information. This knowledge is not obtruded but is reduced to a condition of practical efficiency. Many valuable maxims and warnings and guides to sound mental hygiene will be found scattered through the pages of this handy little volume. It should be for sale in every railroad train, to catch the business man in his hour of leisure, and enforce its useful precepts on a class in especial need of them.

Dr. Wood thinks it probable that nervous diseases are increasing. The general causes of nervous trouble he considers under the heads of exposure and dissipation. He treats of the effects of emotional and intellectual overwork; of the difference of labor power in the sexes, and of rest in labor, in recreation, and in sleep. Dr. Wood thinks the anemia theory of sleep improbable, and believes that sleep comes from exhausted nervous energy, the lessened flow of blood being the result and not the cause of sleep. T. W. F.

—A petition is circulating in New York against the anti-vivisection bill. It is presented to medical men only. With two or three exceptions all have signed it. Prof. John C. Dalton has been especially active in the matter.

Medical and Surgical Journal.

THURSDAY, FEBRUARY 26, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Osgood and Company, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to
HOUGHTON, OSGOOD AND COMPANY, BOSTON, MASS.

EXAMINATIONS FOR COLOR-BLINDNESS AND DEFECTIVE SIGHT AMONG RAILROAD EMPLOYEES.

MORE than a year ago, at the request of Dr. B. Joy Jeffries, an order was introduced and passed in one branch of the legislature of Massachusetts, that the committee on railroads inquire whether any and (if any) what legislation is necessary in reference to the employment by railroad companies in certain responsible positions of persons affected with color-blindness. As the result of a public hearing, at which Dr. Jeffries appeared, the subject was referred to the board of railroad commissioners for consideration and report. The conclusions of the board appeared in their eleventh annual report, and are well known to our readers.

Last January, at the request of Dr. Jeffries, another order was passed in the lower house, similar to the first, but aimed at the employment of persons not having normal or the average visual power. The board of railroad commissioners did not recommend any legislation on the subject, on the ground that the interest of each corporation is strong enough to insure careful examination, and that its humanity would prevent a company from knowingly employing a person whose defective sight might at any time cause a fatal accident; the board find especial assurance of the wisdom of this position in the present general diffusion of information upon the subject. The commissioners further expressed the opinion that examinations for color-blindness may be properly made by persons not medical experts, and that such examinations will certainly be sufficient if doubtful cases are referred to experts. On this, as on some other points, Dr. Jeffries took issue with the commissioners, and we think very properly. His position is enforced by the strongly expressed testimony of Professors Donders and Holmgren, and by a letter from Dr. Hugo Magnus, which was published in our columns.

The question as now before the legislature may be said to have resolved itself broadly into this: Shall the examination of railroad employees for defects of vision be made compulsory by law; and if so shall these examinations be conducted by experts appointed by the State, or shall it be left to the self-interest and humanity of the railroad corporations to conduct them as may seem for their welfare? The subject is an important one, and should not be left to chance. To be convinced of this it is only necessary to remember that color-blindness exists among railroad employees in Europe to at least three per cent.,

to which must be added other equally serious defects of vision. We hope the humanity and self-interest of the railroad corporations would prove as efficient protectors as the commissioners anticipate. Their opinion on this point is of value. The conclusion, however, that examinations for color-blindness can be properly made by persons not medical experts is undoubtedly erroneous, and if applied to other defects of vision would be still more untenable. An educated man with a fair knowledge of physics could probably conduct an examination for color-blindness in such a way as to enable him to pick out from a number of men all the color-blind, but he would be very apt to include among them others not color-blind. Such a result would bring the system into discredit at the same time that it worked an injustice. When it came to other defects of vision than color-blindness, our examiner would find much greater difficulties. But if the matter is left to the discretion of the corporations the public cannot be at all sure that the examinations will always be conducted by educated men with a knowledge of physics. Cases could be cited in this country where mistakes have been made by ophthalmic surgeons, men who were without special training.

The experience already acquired on the subject, the testimony collected by Dr. Jeffries from abroad, and from such home authorities as the surgeon-general of the United States army, navy, and marine hospital service, all go to show the wisdom of legislation that there may be uniformity of tests, and of the appointment of experts that there may be reliable examinations. We believe the interests of the companies and of the public would both be furthered thereby.

In the long run a uniform examination by experts would be an economy, and as for the rights of the citizen being invaded by such legislation, it ought not to require a very sharp voter to be able to see that too high a price may be paid for even so sweet a thing as personal liberty.

JOHN NEILL, M. D.

PROF. JOHN NEILL, one of the most prominent physicians in Philadelphia, died on February 11, 1880, at his home, of chronic Bright's disease, from which he had been suffering for a long time. About a year ago he lost his sight from albuminuric retinitis and atrophy, but he had been an invalid for even a greater length of time. He was a man of great ability and rare culture, and was highly esteemed by the entire community.

Dr. Neill was graduated from the University of Pennsylvania in 1840. In 1845 he was made demonstrator of anatomy, and in 1874 he was appointed to fill the chair of clinical surgery at the university, but was obliged to resign on account of failing health in 1877. He had previously occupied the chair of surgery in the old Pennsylvania College. In 1861, Dr. Neill was appointed surgeon in charge of the military hospitals in Philadelphia, and organized the first eight general hospitals in this city. The following

year he was commissioned surgeon of volunteers, and in 1863 was appointed medical director of the forces from Pennsylvania, and the same year was breveted lieutenant-colonel for merit. He had also served at various times as surgeon to the Wills, Presbyterian, Pennsylvania, and Philadelphia (or Blockley) hospitals, and to the Deaf and Dumb Institution. He established the hospital at Dickinson College after the bombardment of Carlisle, and also the hospitals at Hagerstown. Dr. Neill was the first curator of the College of Physicians, and the founder of its museum. During the prevalence of cholera he made some beautiful preparations with minute injections, upon which was based the report on cholera, published in the *Transactions of the college*.

Dr. Neill contributed frequently to the medical press; articles from his pen are found in the *Medical Examiner*, the *American Journal of Medical Sciences*, and the *Transactions of the College of Physicians*. He had also written monographs on the arteries, veins, and the nerves, but is best known to students as one of the authors of Neill and Smith's Compendium.

Professor Neill possessed great natural ability and rare culture, and his attainments and attractive personal qualities gave him a high position both in society and in the ranks of the profession.

THE NEW YORK STATE BOARD OF CHARITIES.

THE thirteenth annual report of the New York State Board of Charities, which has just been submitted to the legislature at Albany, affords as conclusive evidence as any of its predecessors of the necessity for the existence of such a body, and of the admirable manner in which it is systematically and gradually correcting abuses that have long existed, and carrying out reforms that will eventually, it is hoped, bring about a complete revolution in the administration of public charities in the State.

The present report shows that during the past year extensive visitations have been made by the board both to the county poor-houses and all the state institutions. During the year ending November 30, 1878, the number of inmates in the county poor-house, was 22,131, and of individuals temporarily relieved 101,140, while in the year ending November 30, 1879, those figures were respectively 18,924 and 62,673; which shows a gratifying decrease. The expenditures for in-door support were \$592,874.33, and for temporary relief \$625,546.42; the average per capita expenditure for the year, above the income of the farms, being \$87.78. The average amount expended upon each person temporarily relieved was \$9.08; while the income from pauper labor amounted to only \$2.16 a head for the year.

The city almshouses belong to New York, Brooklyn, Newburgh, Kingston, Poughkeepsie, Utica, and Oswego, and are organized under special statutes. The number of inmates last year was 39,001, and the number temporarily relieved 17,179; making a total

of 56,180, as against 58,072 in the preceding year. The highest point of expenditure was reached in the county institutions in 1868, and in those of the cities in 1870. The increase of insane inmates from 1868 to 1879 was 2499 and this in spite of the fact that a large number were transferred from time to time to the state institutions for the care of this class.

The statistics thus summarized, in connection with others not given here, lead to these conclusions; first, that there has been a large increase in the pauper insane within twelve years, — much beyond the ratio of increase in the population; second, that there has been no increase in the volume of pauperism arising from other causes, but, on the contrary, a relative decline; and, third, that the latter result has been attained by the attention given to the subject by the board and by organized efforts in other quarters, securing better officials and more watchfulness and frugality. The investigations of the board induced the belief that much of the existing pauperism may be done away with by the adoption of appropriate measures, and among the agencies which it suggests for this purpose are the following: (1.) The poor-houses should be so planned as to enforce a complete separation of the sexes and a thorough classification of all inmates. (2.) Admissions should be guarded by the most stringent rules, so that the easy entrance which leads to dependence may be stopped. (3.) A thorough system of industries should be maintained in every poor-house, leading to better discipline, more happiness, and larger income. (4.) Provisions should be made for the prompt and effective treatment of all sick poor, which in many cases will save the patients from becoming permanent burdens upon society. (5.) This prompt treatment should be especially secured to the insane, since in that disease above all others the hope of recovery decreases more certainly as it progresses. (6.) The care and training of dependent children should be provided separately from that of adult paupers, and for this purpose orphan asylums should always be accessible, from which they can be placed directly in family homes. (7.) The administration of out-door relief should be rigorously guarded and prevented from becoming indiscriminate and continuous. (8.) The legal settlement of all applicants should be carefully examined, so as to place the responsibility of their support where it properly belongs.

There are 158 orphan asylums and homes for the friendless in the State, and the whole number of persons in their care last year was 36,331. The advantages of caring for dependent children in such institutions rather than in poor-houses are strongly urged by the board.

The hospitals in the State are then taken up. Beside the several general public hospitals, there are thirty-six general and twelve special hospitals under the control of corporate associations. The whole number of patients treated in them during 1879 was 18,625, and their efficiency is warmly commended. There has of late years been a large increase in the number of dispensaries, and the total is now forty-one.

On the 1st of October, 1879, there were 9015 insane in the various institutions of the State, as against 8688 at the same period of 1878, and 7921 in 1877. In 1871 the number was 5032, so that since then there has been an average annual increase of 9.89 per cent., while the increase of population has been only 1.67 per cent. Including those patients who are kept in families, the number of insane in the State at the beginning of the fiscal year was 10,597, or one to every 472 of the population. The accommodations for the chronic insane are now entirely inadequate, and the attention of the legislature is called to the urgent necessity for the enlargement of the state institutions.

The report closes with a vigorous protest against the practice of many cities and towns of different countries in Europe of sending to this country their blind, idiotic, crippled, epileptic, lunatic, and other infirm paupers, in order to avoid the burden of their support. The investigations that the board have made upon the subject have clearly established the fact of this practice, European countries finding it cheaper to deport these dependents than to maintain them at home. As they are incapable of providing for themselves, once landed here the burden of their support falls on the city and state authorities. The board has therefore directed the attention of Congress and the general government to this wrong, but in the mean while it proposes to send back immediately every such pauper that is brought to our shores.

In connection with the portion of the report devoted to the subject of the care of dependent children, it is interesting to note that a large meeting of the most influential residents of Westchester County, which lies just north of New York, has been held within the last few days at the rooms of the State Charities Aid Association in that city, for the purpose of deciding upon the best methods of providing for the pauper children of the county. At this meeting there was unanimously adopted an address to the superintendents of the poor of Westchester County, which states that, in view of the increase of pauper children in the county, and the increased expenditure which their maintenance as paupers necessitated, a number of ladies and gentlemen, citizens and taxpayers of the county, had agreed to form themselves into a committee for the purpose of seeking permanent homes for these children, thus relieving the county of their support, and for establishing a temporary home where they could be received until they were so placed. This temporary home was then organized on the spot, with an efficient board of managers, and half the sum required for the work was immediately subscribed by those present. This good example, it is to be hoped, will be emulated by the citizens of other counties; for however desirous superintendents of the poor may be to keep such children from contact with adult paupers, thus far they have failed to do so. At Randall's Island, where a nursery was established with the most honest intentions, it became at last so permeated with workhouse and almshouse influences that at the time it was investigated by the State Board of Charities,

of 74 women in charge of 1300 children, 67 were of intemperate habits, 23 were paupers, and 51 belonged to the criminal classes.

MEDICAL NOTES.

—"Spencer Wells," says the *British Medical Journal*, "has performed forty consecutive operations of ovariectomy without one death."

—At the University of Edinburgh in 1878, of 262 candidates at the first examination 25.9 per cent. were rejected; of 165 at the second the rejections amounted to 35.1 per cent; at the final examination 144 students appeared, and eighteen per cent. were rejected. This is considered a proof of the severity of the examinations.

—According to the *Maryland Medical Journal*, it is asserted that there are not less than two thousand cases of feticide in Maine annually, and that it is impossible to get an attorney to prosecute or a jury to convict an abortionist.

—*Guy's Hospital Gazette*, which was suppressed by its editors because of interference on the part of the lay treasurer of Guy's Hospital, has reappeared. The treasurer wished to act as a censor. To this the editors naturally would not submit. They now have their way.

—Jean Charles Chenn, the eminent physician and naturalist, and Chevalier, a distinguished French chemist, are dead.

—Lister, of London, and Deronbaix, of Brussels, have been elected foreign corresponding members of the Paris Académie de Médecine.

—Dumontpallier, of Paris, asserts that pain located at one point of the body yields to an injection of water, or merely a simple puncture, made at a corresponding point on the opposite side. This procedure he has practiced in neuralgias, in acute articular rheumatism, and in rheumatic or toxic neuralgia. So soon as irritation has been produced on the sound side, the patients have acknowledged a diminution, and often a complete cessation, of the pain on the affected side.

—Dr. William Goodell thinks laceration of the cervix uteri is frequently caused by premature rupture of the bag of waters. It is likewise produced by the forceps and, again, by attempts to push the upper lip of the os over the child's head. One sixth of Goodell's women patients have laceration of the cervix. He thinks this is due to too much interference.

—Dr. Smidowisch recommends apomorphine in croup and acute laryngitis. He has used it with success in four cases.

—Madame de Rémusat tells this story of Corvisart: "The emperor having, for the moment, given up the divorce, but always taken up with the desire for an heir, asked his wife if she would accept one that belonged to him only, and feign pregnancy so that everybody should be deceived. She was far from refusing herself to any of his fancies in this regard. Then Bonaparte sent for his physician-in-chief, Corvisart, in whom he had extensive and merited confidence, and

confided his project to him. 'If I succeed,' said he to him, 'in assuring myself of the birth of a boy who will be my own son, I wish that, as witness of the confinement of the empress, you will do everything necessary to give this ruse every appearance of reality.' Corvisart found that his honor was compromised by this proposition: he promised inviolable secrecy, but refused to lend himself to what was asked of him. It was only a long time afterwards, and since Bonaparte's second marriage, that he confided this anecdote, while attesting the legitimate birth of the King of Rome, upon which doubts entirely unjust have been thrown."

— Dr. Pnpi, in *La Spérimentale*, reports successful treatments of an erectile tumor by the repeated injection of a ten per cent. solution of chloral. The cure was effected in five days.

— In Chicago it is believed that one fourth of all the sick receive medicines and advice gratuitously through dispensaries.

— Chaillé says, "The history of the American state legislation upon the regulation of medical practice conclusively proves: (1.) Laws which debar homœopaths, eclectics, and other practitioners of any special or exclusive system of therapeutics from the practice of medicine cannot be enforced if enacted. (2.) No laws have yet established a satisfactory method to determine the qualifications necessary for a practitioner of medicine. (3.) No adequate measures have yet been devised to inflict the penalties of the law on its violators.

— Dr. Corilleau, of Paris, recommends a new remedy for diphtheria, namely, oxalic acid. He gives it thus: oxalic acid, a gramme and one half; syrup of orange, thirty grammes; infusion of green tea, one hundred and twenty grammes. Dessertspoonful every three hours. Corilleau lost but one of the eighteen cases in which he adopted this treatment.

— The *Journal de Médecine* announces the rather remarkable fact that in some French lead works it was observed that two of the many workmen drank a large quantity of milk every day, and were not affected by colic. The general use of milk was adopted throughout the works, and lead colic ceased to occur.

— There are six baronets in the medical profession in England: Gull, Paget, Jenner, Watson, Burroughs, and Thompson.

— Dr. Strauss says that a differential diagnosis of central from peripheral paralysis of the face may be made as readily by the use of jaborandi as by the constant current. In using the latter, if the disease be central, the muscles in the paralyzed locality contract; they fail to respond if the facial nerve be involved. When jaborandi is given, if the affection be central, sweating occurs on both sides of the face. If the nerve trunk be diseased, no sweating occurs on the paralyzed side.

— The *Chicago Medical Journal and Examiner* says that Messrs. Decaisne, of Paris, have made certain experiments upon the head of a decapitated criminal, which demonstrate that the popular ideas respecting the survival of consciousness after the act of execution are totally erroneous. The traditions which

teach that certain heads have exhibited such phenomena, as winking of eyelids, biting of lips, blushing, etc., belong evidently to the category of the ghost stories of the nursery. The Messrs. Decaisne, although experimenting upon the head immediately after the descent of the fatal axe, were unable to elicit the faintest evidence of vitality.

— Dr. Seguin reports the case of double dislocation of the kidneys in a woman, with voluntary control over these organs, the patient being able to cause the loosened kidneys to descend and present behind the anterior abdominal wall.

— Cohnheim favors the view that all tubercular processes are of infective origin. Schüppel believes them to be caused by bacteria, and therefore recommends anti-parasitic remedies.

— Winternitz says that injections of cold water into the rectum rapidly reduce the temperature of the stomach, and suggests that they may be useful in gastric disorders.

— The *North American Review* for March contains articles on the Third Term, Civil Service Reform, and our Political Dangers, which are worthy of attention.

— In his book on the pay hospitals of the world, Mr. Henry C. Bardett takes the Massachusetts General Hospital as the representative of the American system, partly, as he says, because it is one of the best known and best regulated hospitals in America, and partly on account of the great pains which the authorities, through their representative, Dr. J. H. Whittemore, have taken to supply a full account of the American system of hospital management.

PHILADELPHIA.

— The new State Hospital for the Insane (at Norristown) for the southeastern district of Pennsylvania is now nearly equipped for receiving patients. Fearing that political influence might place an incompetent man in charge as superintendent, the board of trustees were memorialized by a number of prominent members of the Philadelphia profession, urging the vital importance of selecting "a physician of thorough experience in the hospital treatment of mental disease, of high intellectual qualities, and above all unimpeachable reputation as a man of the purest moral character, commanding that confidence which should be reposed in those charged with such grave public responsibilities." At a recent meeting of the board, Dr. David D. Richardson was chosen to fill the position of superintendent, an appointment that thoroughly met the wishes of the profession, as Dr. Richardson has been in charge of the insane department of the Philadelphia Hospital for a number of years.

WASHINGTON.

— Recently, within a few weeks, the supreme court of the District of Columbia decided that the ordinances and regulations adopted by the former board of health and the present health officer of the district could not be enforced by fines and penalties, and were therefore null and void; in consequence, the health officer, through the commissioners, has made an appeal to Congress for their speedy legislation, in view

of the presence of small-pox and the necessity for the vigorous enforcement of sanitary laws.

MEDICO-LEGAL.

— In the supreme court of Illinois, in an action to recover the amount of a life insurance policy on the life of a man who died of delirium tremens, it was decided that "in the cross-examination of a medical expert it is competent to read to him from medical works a description of the disease of which he has testified the assured died, and then to ask him whether he agreed with the authors. Such a use of these books is not reading them in evidence to the jury."

— The Nebraska courts have decided that temporary insanity produced immediately by intoxication does not destroy responsibility where the accused, when sane and responsible, made himself voluntarily drunk.

— A surgeon appointed by the commissioner of pensions to examine applicants for pensions is not an officer of the United States. He is not appointed by a head of a department of the general government.

Miscellany.

THE MEDICAL CONGRESSES AT AMSTERDAM AND BADEN-BADEN.

MR. EDITOR. — Good fortune having brought me to Amsterdam and to Baden-Baden in time to attend the meetings of the International Medical Congresses, I thought a short description of the proceedings might interest some of your readers. The first congress took place in Amsterdam, and was made especially interesting by the presence of such men as Virchow, Lister, Donders, Rosenstein, and others whose names are well known on both sides of the Atlantic. The object of these meetings is to bring the medical men of all sections together, part of the time (usually the forenoons) being spent in discussing medical questions, the nature of which is announced beforehand, the remainder of the time being given up to friendly intercourse between the members, theatres, concerts, expeditions to various points of interest in the neighborhood, and other entertainments offered by leading inhabitants of the spot chosen for the congress. The meetings last usually one week.

In Amsterdam, the first evening was devoted to a reception, held in the large hall and gardens of the Zoological Society; a somewhat informal affair, to enable the members to meet and "break the ice," as it were, for the ensuing week. The next afternoon (Sunday) the opening address was made by Professor Donders, the president of the congress, extending a welcome to all, followed by the election of officers for the ensuing year and the division of the congress into its various sections, each section receiving its allotted room for the discussion of its special subject. In the evening, a large reception, tendered by the mayor on the part of the citizens of Amsterdam, was held in the city hall; for a marked feature of these congresses is that leading members of the laity take part in the public exercises, and are strenuous in their endeavors to make the week one of pleasure as well as of benefit to their medical visitors.

The following morning the regular business of the

congress began, papers being read and discussed in the various sections, the exercises lasting from three to four hours. These discussions took place every morning, with the exception of Wednesday, the whole of which was devoted to an expedition to the grand canals lately constructed by the government. On three afternoons public addresses were given in the general assembly hall by eminent medical men, the most interesting event being the ovation accorded to Lister on the afternoon of his public speech. Professor Donders, in a few words, introduced him to the audience, and as he stepped forward on the platform the hall rang with cheers and applause which lasted some minutes. His subject, as might naturally be supposed, was Antiseptic Surgery, and the modest, quiet force shown in his defense of his doctrines must have convinced every one there that it was no mere enthusiast who spoke, but a man who, entirely convinced of the correctness of his views through untiring labor on his own part, was ready to defend a method which, when conscientiously and correctly carried out, has been and can be of incalculable benefit to suffering humanity. At the close of his speech Donders paid him a graceful tribute, and again the hall resounded with prolonged cheers and applause.

I should have said that to become a member of the congress each one must give his name at the bureau of the congress and pay a sum of about four dollars, for which he receives a card admitting him to all the public performances given during the week and to all exercises held in the rooms of the congress. The evenings were always devoted to entertainments in the form of concerts in the halls or gardens and to performances in the theatre.

The following week the *Versammlung der Naturforscher und Aerzte* took place in Baden-Baden. The unusual beauty of the surrounding country and of the town itself, as well as the many names of celebrated men present, made this congress especially attractive. Langenbeck, Recklinghausen, Spencer Wells, Kussmaul, Friedreich, Ziemssen, and others made an array of names which alone would attract one if only to look at such an assemblage. The exercises took place in the magnificent rooms of the *Conversationshaus*, the gambling hall of former years, and were conducted on much the same principle as those in Amsterdam. I can conceive of no more delightful combination of "business and pleasure" than was offered in that week: the mornings and three or four afternoons devoted to listening to discussions on medical subjects by the medical lights of the world, the leisure time being divided between delightful walks on the surrounding hills, listening to the music on the *Curplatz* opposite the *Conversationshaus*, the gem of a theatre, and expeditions to Heidelberg, Strassbourg, and the Black Forest, all not far distant.

The marked features of these assemblages are, first, the interest shown throughout Germany, and Europe in fact, by the medical profession, an example which we should do better in our American Medical Association to emulate; second, the interest shown by the laity in the town or city chosen for the place of meeting; and, thirdly, the judicious division of the time between medical work and entire relaxation, thus making the congress doubly attractive and beneficial to all its members.

Of the advantage of such meetings to the advancement of medicine there can be no doubt; for apart from the benefit arising from the public discussions by prom-

inent medical men, sectional prejudices are more likely to be worn away, and a feeling of personal sympathy between the members established, hence giving each one a greater interest in the works of the others. Let us hope that the interest shown in our own American Medical Association will continue so to increase that it may some day be to us what the similar congresses are to the medical profession in Europe.

V. Y. B.

LEIPZIG, January 20, 1880.

THE PROPOSED MEDICAL ACT.

MR. EDITOR,—In the report of the Suffolk District Medical Society in your issue of February 19th, I find an abridgment of some remarks of mine so reported as to appear ridiculous. I did not simply state that the proposed law "was ridiculous and unwise," but after a somewhat extended argument I did reach what seemed to me a logical conclusion, that the law was both ridiculous and unwise. I did state that the law was opposed to the reasonings of Adam Smith and Herbert Spencer, and compared their authority with that of the individuals from whom Drs. Cushing and Wigglesworth exhibited numerous certificates of approval of the law.

One word in regard to Dr. Wigglesworth's answer that the "Social Science Association had not inaugurated this reform as philosophers, but as public-spirited citizens." No one will dispute his statement; but let me ask if, considering the legislative enactments of the Massachusetts legislature, it would not have been better if a greater number of laws had been proposed by "philosophers" and fewer by public-spirited citizens, who have crowded our statute-books with non-sensical statutes (dead and alive) until the lawyers cannot tell us the law. If Dr. Wigglesworth thinks that our profession will figure better in this company of public-spirited citizens than in that of philosophers, I can only deprecate his taste.

Respectfully yours,

D. HUNT.

THE CODE OF ETHICS.

MR. EDITOR,—Does the acceptance of a code of ethics by the council of the Massachusetts Medical Society make it binding upon the Fellows, unless it is accepted at the annual meeting of the Fellows?

From the account of the action of the council in the JOURNAL it is not clear, I think, whether the vote is to be discussed by the society next summer or not.

I cannot find in the prescribed duties of the councilors (By-Laws XVII., XVIII., XIX.): Digest of Acts of Commonwealth, relating to Massachusetts Medical Society, XVI., XVII., XVIII.) that the enactment of a code is included. Although the council may assume this power, it is certainly desirable that the style of legislation exhibited by the council in regard to the admission of women be not continued. The council decreed last autumn that women should be admitted to the Massachusetts Medical Society. This was accepted by the community, was quoted in the daily press and by President Eliot in his annual report. The council have since practically admitted that they had no legal right to enact such a decree,—a fact which should have been thought of before placing themselves and the society in a ridiculous position before the public.

If, hereafter, a Fellow be expelled from the society for non-observance of the code, can he not claim that it is doubtful whether the vote of the council in this matter binds the Fellows of the society unless the code is adopted by the society? A FELLOW.

THE ADMISSION OF WOMEN TO THE MASSACHUSETTS MEDICAL SOCIETY.

MR. EDITOR,—In your comments in the last number on the action taken by the last meeting of the councilors upon the woman question, you justly say "that the question stands at the present moment precisely as it did before any action was taken." It is interesting to recall the fact that in 1873, "before any action was taken," the councilors appointed a committee to obtain legal advice upon the very question now at issue, and that at the annual meeting, June 3, 1873, this committee presented to the councilors the written opinion of Messrs. Hoar and Putnam.

As the full text of this opinion has never been printed, so far as I know, its publication in your widely read columns would be useful at the present time. A copy is inclosed. Very truly yours,

G. E. FRANCIS.

WORCESTER, February 14, 1880.

BOSTON, March 11, 1873.

CHARLES E. BUCKINGHAM:—

DEAR SIR,—We have carefully examined the question raised by your communication of February 20th in relation to the application of Miss Susan Dimmock to the Massachusetts Medical Society, and we are of opinion:

(1.) That the society may, if it see fit, prescribe as a qualification for membership or license that the candidate shall be of the male sex.

(2.) That it has not yet done so, by its by-laws submitted to us (edition of 1861).

(3.) That in the absence of any such regulation by the society it rests with the examiners or censors to whom the application is made whether they will approve the licensing of a woman to practice, and that it is competent for them to reject an applicant on the ground of her sex, if in their judgment that is a disqualification for the practice of medicine or surgery.

(4.) That in the absence of any by-law of the society excluding women from examination, if any woman shall be licensed to practice by the proper officers of the society, she will thereupon be entitled to membership of the society. Very respectfully yours,

(Signed) E. R. HOAR.

(Signed) GEORGE PUTNAM, JR.

MR. EDITOR,—In your issue of February 12th, page 157, in reporting the discussion pending the referring of the question of admission of women to the general society for ratification, I think your reporter misapprehended one element in the discussion, namely the relation of *he* to the question of sex as applied to our charter and by-laws. In this discussion of February 4th, Dr. Millet suggested that it might be necessary to invoke legislative authority before women could be admitted. I then suggested that to the mind of a former council that question had been settled, namely, that of sex, which I understood Dr. Millet to refer to. Permit me here briefly to review this point. When the

question of the admission of women to the society was first agitated, it was urged that they were ineligible by reason of the spirit and language of our charter, which contemplated the association and incorporation only of men. Digest, Sections XI., XXVII., and XXVIII. were quoted to sustain this view, the pronoun *he* always being used in referring to person. On the other hand, it was contended that the scope of both charter and by-laws was ample to cover both sexes, and Digest XXIII. and By-Law I. were quoted in defense of that view. Finally, it was voted to refer the question of woman's eligibility by reason of sex to Judge Hoar, then senior counsel of the society, who decided her eligible. It was this decision to which I referred in speaking to the question February 4th.

J. R. BRONSON.

ATTLEBORO, February 17, 1880.

SCANZONI IN RHYME.

A SMALL 12mo of forty-two pages has recently (1879) been published in Bern and Leipzig, as written by "Campolongo," and entitled "Der Kleine Scanzoni. Repetitorium Gynækologium Hystero-poeticum." This gives in pleasing verse the lessons taught by Scanzoni on the diseases of women, and is not in ridicule, but conveys the sense of the lessons very agreeably. A few extracts will show the style quite well:—

SPECULA.

Für Seitenlage praktikabel
Ist Sims' einarm'ger Entenschnabel;
Und geht's an's Operiren scharf,
Man Simon's Speculum bedarf.
In England und Amerika
Gibt's täglich neue Specula;
Doch bleibt es stets die alte Leier:
Was complicirt, das ist auch theuer;
Auch denkt ein Practicus, ein echter:
Je complicirter, desto schlechter!

Und müsst Ihr schlitzen auch ein Hymen,
So denkt gelassen: non est crimen!
Nur übet Mass und Billigkeit,
Und treibt die Spannung nicht zu weit;
Der Heilkunst Segen wird zum Fluch;
Bedenkt man nicht den alten Spruch:
Was du nicht willst, das man dir thu,
Das füg' auch keinem Andern zu!

HYMEN.

Das Hymen ist 'ne Tugend, die
Sich leider lässt erheucheln nie,
Und die aus diesem Grund fürwahr
Sich finden lässt nur äusserst rar.
So Mancher suchte sie im Dunkeln
Und fand statt ihrer nur — *Karunkeln!*

The book closes with a significant wood-cut, having for a base the female pelvis, with a snake entwining itself through the obturator foramina; in the left foramen a sprig of roses, and in the right a bunch of nettles.

INTESTINAL ANTI-PERISTALSIS.

MR. EDITOR.—The recent statements and discussions which have appeared in print concerning the anti-peristaltic action of the intestines in carrying injected materials, enemata, beyond the ileo-cæcal valve even into the stomach makes of special interest certain statements in a little French work published

in Paris in 1878, and entitled *L'Instrument de Molière; Traduction du Traité de Clysteribus de Regnier de Graaf* (1668). In paper, type, and illustrations, this work is an edition of *luxu* of a translation, as its name implies, of the treatise on injections, or clysters, as the old term puts it, by that De Graaf whose name comes down to us in connection with the Graafian follicle. A handsome portrait of De Graaf forms the frontispiece, while interspersed through the work are little cupids, who furnish the head and tail pieces in a manner at once very Frenchy and suggestive of the matter contained within the text. The object of the work, which is prefaced by a full notice of the life and writings of De Graaf, and filled with copious and interesting notes, seems to be to introduce the use of a long and flexible tube, invented by the author as an aid in giving and receiving injections without exposure of person. But the part of most interest here is the assertion that a number of cases have demonstrated that, contrary to the nature of things, the valve of Bauhin (ileo-cæcal valve) is found relaxed during an anti-peristaltic action of the intestines, so that clysters pass out by the mouth, and that this fact is mentioned by Galien, Sennert, Paré, Bartholin, and many others, of whom some affirm that suppositories have been ejected in the same way. Sennert is quoted as giving a case of a young girl of twelve years, "souffrant de la passion iliaque," who could not only retain nothing by the rectum, but also vomited violently the clysters almost as soon as received. This state of things lasting for three days, a long suppository was introduced, and in the time which it took to recite a Pater Noster and an Ave Maria, to quote the quaint language used, it was rejected by the mouth; a second, retained by a thread, was vomited, the thread being broken; a third, attached by four stronger threads, took the same course; a fourth produced so violent a movement (of the intestine?) that the mother removed it in fear that it would follow the others. The girl was finally relieved through the use of very fat bouillon, which triumphed over the excitability of the organs.

W. L.

ANÆSTHESIA BY ETHYL BROMIDE.

MR. EDITOR.—The following case, in which the above named-drug was used, is of interest to the profession:—

The patient, under the care of Dr. C. J. Blake, at the Massachusetts Charitable Eye and Ear Infirmary, a ship's cook, aged thirty-five years, was suffering from chronic otitis media purulenta, right ear. Four weeks ago there was an acute exacerbation of the disease after exposure at sea. There was sleeplessness and loss of appetite. Considerable oedema and erythema below and behind the auricle. Great tenderness on pressure, with a sense of fluctuation over the mastoid process. Wilde's incision was advised.

The operation was done at 2.10 P. M. on February 4, 1880, by the house interne, assisted by the writer; patient reclining with head raised. Pulse 92.

About sixteen cubic centimetres (half a fluid ounce) of ethyl bromide were poured on a small folded towel, and held to the nose of the patient for two and a half minutes, the breathing continuing regular. At the end of this time anaesthesia with relaxation of the muscles was produced. The incision, two centimetres (three

quarters of an inch) in length, was then made vertically, about one and a half centimetres behind the auricle (over the mastoid process of the temporal bone) through the integument to the bone.

During the time that the incision was being made there was no movement of the patient.

Voluntary motion with an apparent restoration of consciousness succeeded, in two minutes, the making of the incision. In seven minutes after the first inhalation of the ethyl the patient talked rationally about the operation, and said that he felt the knife, as if it were the pressure of a finger drawn over the skin,

but that there was no pain. The window near by having been opened and cold, fresh air supplied, the patient soon became chilly and trembled, saying that he felt weak. The window was then closed, ammonia given by inhalation, and blankets were placed over the patient. He said at the end of fifteen minutes, the trembling having entirely ceased, that he felt easy and able to recline comfortably, which he had not done for many hours previous to the operation, on account of the extreme tenderness in the neck. There was no nausea.

Two thousand five hundred and twenty-two deaths were reported; 810 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 470, consumption 396, lung diseases 366, diphtheria and croup 201, scarlet fever 75, typhoid fever 50, measles 44, whooping-cough 27, diarrhoeal diseases 26, malarial fevers 17, erysipelas 11, small-pox seven, cerebro-spinal meningitis six, typhus fever six. From measles, New York 21, Philadelphia six, Brooklyn and Chicago five, St. Louis and New Haven three, Lowell one. From whooping-cough, Pittsburgh five, New York three, Philadelphia, Brooklyn, New Orleans, and District of Columbia two, Chicago, St. Louis, Baltimore, Boston, Cleveland, New Haven, Charleston, Somerville, Gloucester, Marblehead, and Palmer one. From malarial fevers, New York eight, St. Louis and New Orleans three, Chicago two, Brooklyn one. From erysipelas, Brooklyn three, New York and Philadelphia two, St. Louis, Cincinnati, Nashville, and Newburyport one. From small-pox, Philadelphia three, District of Columbia and Worcester two. From cerebro-

spinal meningitis, Philadelphia two, New York, Chicago, Lynn, and Marblehead one. From typhus fever, Chicago four, Philadelphia and Baltimore one. One hundred and sixty-four cases of measles, 58 of diphtheria, nine of whooping-cough, and three of typhoid fever were reported in Brooklyn; diphtheria 48, scarlet fever six, in Boston; diphtheria 13 in Milwaukee; diphtheria seven, scarlet fever six, in New Bedford. Philadelphia, Washington, and Worcester continue to report deaths from small-pox; one case was reported in Cleveland. Systematic vaccination was begun in Worcester on the 15th inst.

The total number of deaths reported shows a considerable increase over the previous week; of deaths under five as large a decrease. Diarrhoeal diseases were less fatal, and to a less degree also scarlet fever and diphtheria. Lung diseases, consumption, typhoid fever, measles, and small-pox caused more deaths. In 37 cities and towns of Massachusetts, with an estimated population of 958,060 (population of the State about 1,690,000), the death-rate was 21.82 against 20.41 and 20.17 of the previous two weeks.

In 51 cities and towns of Belgium there were 140 deaths from acute lung diseases, consumption 81, diarrhoea 49, small pox 35, diphtheria and croup 10, fever nine, whooping-cough eight, measles three, scarlet fever two. Brussels death-rate 22.5; Antwerp 28.5; Ghent 30.4; 24 larger towns 33.7; 23 smaller towns 31.5. In the 20 chief Swiss towns acute lung diseases continued

widely prevalent and fatal, diphtheria next in order and increasing; diarrhoea and fever also prevailed. There was only one death from small-pox (Basle), and one from scarlet fever.

The meteorological record for the week in Boston was as follows:—

A NEW REMEDY IN THE TREATMENT OF DIABETES.

BY J. Y. DALE, M. D., LEMONT, PA.

I SHOULD like to bring to the notice of the profession a remedy which has been remarkably efficient in my hands in the treatment of diabetes. It was first brought to my notice in 1876 by a medical friend, who had used it with great success. It is the nitrate of uranium, given in doses of one or two grains three times a day. A year ago I treated a case in which this was the only medicine prescribed, and in connection with appropriate diet the quantity of urine was reduced from two and a half gallons per diem to a quart in less than a month, with a corresponding improvement in all the other symptoms.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM FEBRUARY 14, 1880, TO FEBRUARY 20, 1880.

HALL, J. D., captain and assistant surgeon. Relieved from duty in Department of Texas, and to report to commanding general, Department of Dakota, for assignment to duty. S. O. 53, A. G. O., February 13, 1880.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE WEEK ENDING FEBRUARY 21, 1880.

MEDICAL DIRECTOR E. SHIPPEN ordered as president of naval medical examining board to convene in Philadelphia March 1, 1880.

Surgeon T. N. PENROSE detached from Naval Hospital, Norfolk, and ordered as member of naval medical examining board.

Surgeon W. J. SIMON to the Naval Hospital, Norfolk, Va.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting will be held on Monday evening next, at eight o'clock, at the hall of the Library Association, 19 Boylston Place. Reader, Dr. J. J. Putnam. Subject, A Series of Cases Characterized by "Numbness of the Hands."

FREDERICK C. SHATTUCK, M. D., Secretary.

SUFFOLK DISTRICT MEDICAL SOCIETY. — A regular meeting will be held at the hall, No. 19 Boylston Place, on Saturday evening, February 28th, at seven and a half o'clock. A paper will be read by Dr. J. H. Warren on Cases of Hernia operated upon for Radical Cure by injecting the Internal Rings. Disputants, Dr. T. Waterman and Dr. E. H. Bradford. Dr. Hamilton Osgood will exhibit "a new sanitary trap." All members of the Massachusetts Medical Society are cordially invited to be present and take part in the proceedings.

T. M. ROTCH, M. D., Secretary.

GYNECOLOGICAL SOCIETY OF BOSTON. — The next regular meeting of the society will be held at seven o'clock, P. M., on the first Thursday of March. Paper by W. S. Brown, M. D. Profession invited.

HENRY M. FIELD, M. D., Secretary.

PROF. B. G. WILDER, of Ithaca, N. Y., desires to consult Swan's Illustrations of the Comparative Anatomy of the Nervous System, and will be thankful for information as to where a copy may be found.

PRESLEY BLAKISTON, having purchased the general and imported stock of Messrs. Lindsay and Blackiston, together with the series of American Health Primers, will continue the publishing, importing, and retailing of medical and scientific works at his new book rooms, 1012 Walnut Street. Catalogues furnished upon application.

Lectures.

CLINICAL LECTURE.

BY HENRY J. BIGELOW, M. D.,
Professor of Surgery in Harvard University.

[Reported for the JOURNAL.]

LITHOLAPAXY.

GENTLEMEN. — Within ten days we have had two cases of rapid litholapaxy, one of which you saw. After both, the temperature rose from 98° to above 100° F. On the third day it fell to 99° F., and now, three days later, it is normal. This reaction is like that from the effect of a bougie, and the temperature like that of urethral fever. A patient readily recovers from the operation of litholapaxy if we remove from the bladder all the fragments of the stone. In fact, the new method has succeeded beyond expectation.

Small stones are easily ground up, especially if soft, and then come away of themselves. Serious consequences may follow if fragments are left in the bladder. In former times cases that did not admit of lithotripsy had to be cut; likewise those in which, from any reason, lithotripsy was hazardous. A recent number of the London *Lancet* reports a case in which Mr. Smith, of St. Bartholomew, removed four ounces of stone from the bladder of an elderly man, who left the hospital in a week. This is the largest quantity of debris ever removed by litholapaxy.

The operation, of course, is purely mechanical, and any reference to it is chiefly to its mechanics. The principles of litholapaxy and of complete evacuation are pretty well settled and accepted. It is now mainly a question of certain minor details of convenience in the apparatus. I am satisfied that one point which contributes as much as, if not more than, any other to rapid and complete evacuation is the power of regulating and of frequently varying the quantity of water in the bladder. You require just enough water to prevent the *thud* of the slack walls when they are drawn into the eye of the catheter. When you feel that the bladder must have a little more water to distend it. Too little water crowds the fragments together. When there is too much you may have to chase a single fragment a long time.

The arrangement of hose I show you here is the only one that allows the operator to diminish the quantity of water in the bladder without disturbing the apparatus. If one end of this hose—which is not much larger than a pipe-stem—be kept in a tumbler of water it does not in the least interfere with the convenience of the operator. But, on the other hand, it does enable him, by turning the cocks, to vary from one minute to another, if he please, the amount of water in the bladder. There can be no doubt of the advantage of being able to do so.

Another point relates to the size of the tubes. The smallest tube used in litholapaxy is larger than the largest tube that was used for evacuation in previous operations. But you will find that the largest tubes I use are sometimes not preferred by other surgeons. They are in the habit of using a No. 28 or 29 tube, and these often serve the purpose. The fact is this: a stone after evacuation is found to have been mostly reduced to powder and minute fragments. Large fragments are rather the exception. Now, the fine debris may be evacuated through a 28 or 29 tube, though perhaps not

quite so rapidly as if the tube had a calibre of 30 or 31. It then remains only to crush the larger fragments and repeat the process. I prefer a larger tube, when there is no objection to its introduction, because it not only evacuates the dust more rapidly, but at the same time allows me to remove the large fragments without having to crush them.

I am sure that in the end operators will all use a stand to support the weight of the bulb, because it is very inconvenient to hold it through a long operation. But there should be a device (as in the stand I show you here) for supporting the bulb at different heights, which can be varied during the progress of evacuation.

I also think surgeons will connect the bulb with the evacuating catheter by means of an elastic tube, so that one can be moved without the other. This to me is a *sine qua non*.

RUPTURE OF A TENDON.

You have seen this man in the ward. He came to the hospital with a rupture of the long tendon of the biceps muscle of the arm. It is a rare accident, and is well worth examination. The man fell upon his shoulder and disabled it. More than this he does not know. He has been unable to bend the arm freely, but is now recovering the use of it. There is a noticeable difference between the biceps muscles of the two arms. On the affected side, the outer belly, never long, has contracted into an almost spherical mass. You can see how this arm differs from the other by its curiously irregular outline. Flexion is accomplished chiefly by the brachialis anticus muscle. The biceps here shows one tendon running to the coracoid process, but there is a hollow where the outer belly should be. Just above this depression is a little tendinous mass, which seems to consist of the fibres remaining about the outer tendon. When the man entered he felt pain about the shoulder, and when he contracts the biceps there is very decided pain there now. There can be no doubt as to the character of the lesion. I have had a cast made of the arm. The case is rare. I never happened to see one before.

TUMORS UPON THE STERNUM.

Nine months ago a tumor appeared on the upper segment of this man's sternum. When he works he suffers pain. He is employed in a paper store, and his work is mostly lifting heavy bundles. He has never been sick. While taking down a package of paper from a shelf he struck the sternum. At night it felt a little sore. A tumor soon appeared, and has grown slowly. It is not tender, although he feels it when he first begins to work.

Here is a second case. This man is a stocking knitter, and of sedentary habits. In May or June last he first noticed an inflammatory swelling which extended over a part of the sternum. A second swelling came on later at the top of the bone.

In these two cases we have two exceptional and different tumors of the upper part of the sternum. The inflammatory growth is the more common of the two. Coming on about six months ago, it became tender, was opened, and has been discharging ever since. Within a few weeks the upper swelling appeared on the same patient. It fluctuates a little, but is still firm, and is indolent in progress. It is a case of caries of the sternum with abscess, occurring in a man of weak habit and somewhat run down. Its progress has been

so slow that the character of the lesion might still be doubtful but for the fact that we know that caries of the sternum usually goes on slowly, in this way, producing a diffused or firm swelling. Beyond the removal of the carious portion of the bone, I know nothing to do. It is a case difficult to treat to advantage. When the upper swelling opens both will continue to discharge for a long time.

In the other case we have a strong man and a different growth. The tumor is nine months old. Instead of being diffused it is circumscribed and abrupt. It is lobulated, non-fluctuating, hard in consistence, with a sharply defined base. It followed a blow. I think it is not an inflammatory tumor. It is a rarer form of growth, and simulates an enchondroma. It is about as large as a horse-chestnut. There seems to be a crater in the bone where it escaped from the diploe. As to a definite diagnosis, if the growth be inflammatory a few weeks will develop characteristic symptoms in that direction. If it be a neoplasm, other symptoms will declare themselves in an opposite direction. In a word, we cannot now make a positive diagnosis, and must wait. But if it be an enchondroma any operation would be merely palliative.

Original Articles.

CASE OF MULTIPLE MELANO-SARCOMA OF THE SKIN.

BY L. DUNCAN BURKLEY, A. M., M. D.,

Late Physician to the Skin Department, DeWitt Dispensary, New York; Attending Physician for Skin and Venereal Diseases at the Out-Patient Department, New York Hospital, etc.

MR. —, aged twenty-two years and nine months, first came under my care December 17, 1874, when the following history was obtained:—

He had always been healthy as a child with the exception of a few convulsions. His parents are Americans, living, and in perfect health; he resided within thirty miles of New York. Eight years ago he was operated on for a ranula, which had existed since infancy; the ranula still persists, and fills up and discharges from time to time. Six years ago, while watching a barrel in the process of being hooped, something struck him in the outer side of the right eyeball, inflicting a bruise on the sclerotic. No treatment was adopted, other than keeping the eye closed, and very little inflammation followed. Shortly after this a minute black speck appeared on the site of the bruise, which has steadily increased in size. This is now seen as a bluish-black tumor one fifth by one third inch in diameter, slightly elevated, and with dilated veins running to it. Two and a half years ago the first lesion appeared in the skin, just in front of the lobe of the right ear, which enlarged up to the size of half a walnut, and has again diminished in size, until now it is that of a large split pea, movable with the skin; this tumor has never been colored on the surface, but is of the natural hue of the skin. A year later, that is, a year and a half ago, he noticed a tumor on the left side of the chest, in front; this was discolored, bluish-black from the first, and has since disappeared, as have certain other tumors.

About nine or ten months ago one appeared beneath the left arm, which has flattened and remains, of a dark color. The next tumor was situated on the right temple, the size of a large walnut, which was removed

by Dr. George K. Smith, of Brooklyn, June 30, 1874; another small one had been previously removed, June 19th, from the cellular tissues just below the lower lid of the left eye. Dr. Sherwell, of Brooklyn, who saw the case and examined these specimens, reports that there was no discoloration of the skin over this latter tumor, nor any undue signs of vessels in the neighborhood, or any hyperemia. The wound bled pretty freely, but not more than natural. The tumor itself was friable in structure and almost black in color. Microscopically a great excess of pigment matter was found, and many large cells with two or even three nuclei, rendered much more distinct by acetic acid. The tumor removed June 30th had the same consistency and color, and presented the same microscopical appearances.

At this time the fundus of the eye was examined by Dr. Matthewson, of Brooklyn, without finding any morbid appearance or deposit, even in the right eye, originally affected by the first tumor of the sclerotic. The larynx and back of the tongue were examined by Dr. Sherwell and found normal.

During the last nine months the development of the tumors has been pretty rapid, new ones being discovered almost daily up to the present time, while others disappear occasionally. During the past few months the general surface of the skin has been very decidedly darkening, especially that of the face, which now presents much the appearance of that seen in Addison's disease.

The condition of the disease when first seen was thus recorded: The whole surface, from head to foot, is more or less covered with a development of subcutaneous tumors of various sizes and shapes, varying from that of a very small split pea, to an inch and even two inches in diameter. Most of the masses are circular, and occasionally a long one is observed, as on the right forearm, where there is one two inches long by three quarters of an inch wide. Some of the lumps appear to be made up of several tumors closely set together. Most of the tumors are distinctly raised above the skin, to various heights, some being round on top, others quite flat; even those of an inch or more in transverse diameter may be elevated only a quarter of an inch or so above the level, and be quite flat on top. These appear to be such as have reached their height of development and are undergoing absorption.

All of the tumors are decidedly hard and firm to the feel. Some of them are colored, of various shades, from a greenish-brown to a deep blue-black, but most of the tumors externally appear of the color of the skin. Over these latter the skin is quite freely movable, but over those of a dark color, which are really those undergoing atrophy and flattening, the skin is thick, hard, and united with the tumors.

It is impossible to give the exact number of the separate masses, so many smaller ones are deeply imbedded beneath the skin, and can be found only by palpation. When stripped the body appears to be very thickly sprinkled with them; last week his brother counted one hundred and fifty by the eye.

As previously remarked, some of the tumors are now disappearing. After having attained a certain size, or rather height, as apparently subcutaneous tumors, covered with skin of a normal color, they become first of a purplish color, which deepens until of a deep black. While this is going on the tumors seem to flatten, then absorption appears to take place, the surface sinking

and the color fading somewhat, until at present some of the older ones on the chest and abdomen are seen only as flat discolorations, of the level of the skin, presenting a hue much like that of a nitrate of silver stain. The statement is made by the patient and his father, who are both very intelligent persons, that all of these tumors which have undergone this change have previously bled spontaneously or from friction of the clothing. Some of the lumps showed signs of recent hæmorrhage, especially some situated on the legs near the knees; he states that some bleed every night, the sheets being always bloody in the morning. These changes in the tumors are more prone to occur in those on the chest and abdomen, where he is apt to press upon them in his occupation, which is that of an expressman delivering sewing machines.

A very curious condition develops in connection with some of the tumors, notably in those upon the chest and abdomen. During the process of absorption, when the mass has flattened considerably, there appears a ring or collar around the tumor, which is very distinctly marked in a number of places at the present time. This ring is about a quarter of an inch in width, and in some instances hard, slightly elevated, and of a bluish-black; in other places the ring appears simply as a colored band, not elevated, around the central pigmented spot, separated from it by a very narrow portion of healthy tissue. In some instances this ring is seen around tumors over which the integument is slightly if at all colored. The patient asserts that this circle is always formed around a tumor which has become discolored, and also that those which become discolored on the surface always bleed at some time.

The entire skin is of a darkish hue, though not so dark as the face, which has more the appearance of general nitrate of silver staining or of Addison's disease.

His general condition is good; he feels strong and well, with a good appetite. He has lately been gaining in flesh, and has improved in every way under Fowler's solution, which he has taken for five months or more. He has just begun to notice some choking sensations about the throat; of late, also, is restless in sleep.

On examination the liver was found to measure four inches perpendicularly, and to extend an inch and a half beyond the median line. No mesenteric enlargement was discernible on palpation; the skin of the abdomen was so thickly studded with tumors as to render exploration very difficult. The lungs appeared to be perfectly normal on physical examination.

The urine was first examined on June 19th, by Dr. Smith, of Brooklyn, at the time of the first operation. It was then of a brown color. On July 6th Dr. Sherwell reports it as dark colored, strongly acid, specific gravity 1022, with crystals of uric acid, stained of a distinct blue shade, which seemed to intensify on exposure to light.

At the time of the first visit to me the urine was found to be of a coffee-brown color, with a specific gravity of 1020, with urates quite abundant, and a moderate amount of oxalate of lime. Later on the color became at times of a very dark-brown color, occasionally very muddy from the urates. Sometimes it would appear of a much lighter color, as that of sherry wine, and would remain clear for some time. The sediment, which at times was quite abundant, was, besides the urates and oxalates, made up of irregular

pigment masses and particles, largely amorphous; many of them were apparently contained within epithelial cells, from the pelvis of the kidneys; many of them resembled the pigment colloids of Roberts. The quantity was tolerably free when first seen, but later it became much reduced; once only fourteen ounces were passed in the twenty-four hours. The largest quantity secreted in the same time, while under observation, was thirty-eight ounces.

The subsequent history of the case can be told in a few words. The patient rapidly lost in strength and flesh, and the tumors continued to develop anew, and also to undergo the process of absorption and disappearance before described, only the total mass of cutaneous tumors was steadily on the increase. Tumors reappeared in the site of those excised.

Six weeks after he was first seen he was in a greatly depressed state; swelling of the legs had appeared. These were bandaged, but soon his weakness prevented his coming to the office, and he entered Roosevelt Hospital.

On admission to the hospital, April 23, 1875, his pulse was very rapid, 144; temperature 101° Fahr. He complained of great dryness of the skin. The *rauhla* previously referred to was discharging freely; also an abscess in the right cheek, which discharged through the mouth. There were also open abscesses from ulcerated tumors in the vicinity of the right shoulder, on the inner side of the left fore-arm, and several on the right leg. These discharged pus and pigment of an almost solid consistency; there was also an almost constant oozing of blood. The breath was very offensive. Mental powers perfect.

He remained in the hospital about three weeks, and died there on May 16th. During this period the urine showed the same appearances as before noted; it was acid, specific gravity 1018, was dark colored, and contained a trace of albumen. He failed rapidly, becoming more and more bronzed, until at the time of death the general melanic state of the skin was very striking. The temperature rose to 101.75° Fahr. at the highest, remaining thereabout. During the last few nights of life he was delirious, as also at intervals during the day. For the forty-eight hours previous to death he was mildly delirious most of the time, passing his urine and feces unconsciously; the discharge from the bowels was very thin and of a dark-greenish color. He was very restless during this period, and seemed to be in great pain.

Autopsy by Dr. Delafield, May 17, 1875. The entire skin is of a dark color. On the surface of the body, just beneath and in the skin, are seen a great number of tumors from the size of a pea to that of a hen's egg, many of them of a dark purplish-black color. The dura mater is grayish, and on its inner surface coated with a thin layer of fibrin. The pia mater is normal, except for one small pigment nodule. The substance of the brain is not pigmented, and appears normal. On the right eye, in the sclerotic, close to the outer edge of the cornea, is a small black nodule the size of half a grape seed. The interior of the eye appears normal. The pharynx, trachea, and large bronchi are grayish. The lungs are not pigmented; the left lower lobe is oedematous and partly hepatized. The pericardium is distended with clear serum; heart normal. The peritoneal cavity contains purulent serum. The liver and spleen are pigmented, and black nodules are found in the liver. The mucous membrane

of the stomach and small intestines is congested and coated with mucus. The cervical, bronchial, and mesenteric glands are large and black.

RECENT PROGRESS IN ANATOMY.

BY THOMAS DWIGHT, M. D.

THE SCAPULAR INDEX.

THE precise value of this test in anthropology and comparative anatomy is still to be determined, but as it is likely to be discussed for some time a description

of it will not be out of place. The test was invented by Broca,¹ who applied it to various races of men and to an extensive series of animals. Flower and Garson² have used it also for the study of human races and the higher apes. The lines are drawn as follows: AB, representing the breadth of the bone, runs from the centre of the outer border of the glenoid fossa along

the base of the spine; CD connects the highest and lowest points; a third line unites A and D.³ The scapular index = $100 \times \frac{AB}{CD}$; the infraspinous index = $100 \times \frac{AB}{AD}$. Broca found from a study of twenty-three European and twenty-four negro skeletons that the scapular index in the former was 65.91 and the infraspinous 87.79; in the latter the scapular index was 68.16 and the infraspinous 93.88. Flower and Garson found the scapular index of two hundred European skeletons 65.20 and the infraspinous 89.40. Of the observations on lower animals we will mention merely those on the scapulae of gorillas and chimpanzees. It is worthy of note that the latter more closely resemble man, as the following table shows:—

BROCA.

Of 5 chimpanzees, sc. index 68.52; inf. ind. 130.23.

Of 10 gorillas, sc. index 70.38; inf. ind. 126.05.

FLOWER AND GARSON.

Of 21 chimpanzee scapulae, sc. index 69.9; inf. ind. 138.8.

Of 16 gorilla scapulae, sc. index 72.2; inf. ind. 132.5.

From this it appears that in man and the higher apes a long scapula indicates a higher type than a short one. The methods of progression and prehension in animals below the primates differ so much from those of man that the shape of the scapula is very different, and a comparison of the indices of little value.

MUSCLES OF THE LIPS.

In the Report on Anatomy, published in September, 1877, we mentioned some observations on these muscles by Professor Henke. The gist of his paper consisted in so grouping the muscles that they presented essentially a regular diagram for both sides of the upper and lower lips. The triangulares were described as passing into the diagonally opposite quarter of the lips. Thus the fibres of the right inferior triangular muscle could be traced into the left half of the upper lip.

¹ Bulletin de la Société d'Anthropologie de Paris, Tome I, Troisième Série, 1878.

² Journal of Anatomy and Physiology, October, 1879.

³ In the diagram the point A has been put too high. The lines do not cross at a right angle, as would appear to be the case.

Professor Aeby⁴ has recently added some interesting details to our knowledge of the subject. They are for the most part based on sections to be studied with a low magnifying power. The existence of a continuous circular muscle is denied. What we have known as the orbicularis oris is said to consist chiefly at least of the triangulares and the buccinator. The latter forms the body of what we must still call the orbicularis, and lies under the outer red portion of the lips. Flat sections show very beautifully a decussation of fibres from the two sides of the outer part of the orbicularis. Close to the free edge in the part just stated to be formed by the orbicularis this does not occur. A little further off the more superficial ones run into the skin in series of small bundles, crossing similar ones from the other side. At a greater distance no fibres continue in the lip, but all go to the skin. By far the greater number of these fibres cross the middle line. This arrangement is more clearly seen in the lower than in the upper lip. Aebly denies emphatically that the zygomaticus has any share in forming the orbicularis. It ends in the angle of the mouth. As it approaches this point it divides into two bundles. The smaller runs by the triangulares at their crossing point into the skin; the latter, if we understand Aebly correctly, pierces these muscles, and runs into the mucous membrane. Aebly discusses also some fibres running between the skin and the mucous membrane, first described by Klein as the compressor labii.

ANOMALIES IN THE NEGRO.

Professor Turner⁵ records numerous peculiarities of structure met with in the dissection of two negroes. Colored subjects are too common in American dissecting-rooms to attract attention, but it is to be regretted, in the interests of anthropology, that we have not improved our opportunities of searching for peculiarities of structure that might be characteristic of the race. We mention some of the anomalies described by Professor Turner solely on account of their intrinsic interest; there is no reason to consider them expressions of any law. In the first subject muscular anomalies were numerous, though few were very rare. The pectoralis minor, beside being inserted into the coracoid process, gave off a strong band that blended with the capsular ligament of the shoulder-joint. More remarkable was the right brachialis anticus, which arose by a superficial mass from the humerus below the deltoid, and by a deep one from the lower third of the anterior surface of the humerus. The two portions united to be inserted into the coronoid process, but from the deeper one a distinct slip proceeded to the tubercle of the radius. A muscular bundle from the pectineus joined the tendon of the adductor longus. The peroneus brevis, beside its usual insertion, had one to the tubercle on the outer surface of the os calcis. But few anomalies of the vascular system are mentioned, the most remarkable of which is a loop in the deep palmar arch, formed by the splitting of the radial. The most striking peculiarity in the body is described as follows: "From the internal aspect of the left ulna an osseocartilaginous process projected, from the summit of which a fibrous band passed down to the carpus in proximity to the pisiform bone. Under this band a branch of the anterior interosseous artery, which ran downwards along the inner surface of the shaft of the

⁴ Archiv für mikroskopische Anatomie, Band xvi. Heft 4.

⁵ Journal of Anatomy and Physiology, April, 1879, and January, 1880.

ulna, passed to anastomose with the carpal branch of the ulnar artery."

The second subject presented a very rare anomaly, namely, two thoracic ducts. They lay on either side of the descending aorta, each beginning with a perfect receptaculum chyli situated on the first lumbar vertebra. The right duct pursued the normal course to the root of the neck, where it was joined by the other. The termination of the common duct was, unfortunately, lost. The most striking muscular anomaly was a biceps with four heads. One extra head is far from rare, and Henle mentions a case of five heads; still, one of four is perhaps worthy of record. Beside the usual origins, there was one from the inner surface of the shaft close to the attachments of the coraco-brachialis and the brachialis anticus. The other head was smaller, and arose from the lesser tuberosity and the bottom of the bicipital groove. Turner has observed seven previous cases of four-headed biceps.

THE STRUCTURE OF THE SPERMATOZOON.¹

Mr. Heneage Gibbes publishes some very curious observations on the spermatozoa of several vertebrate animals, and promises to treat of human ones in another paper. He has found the following parts in the living spermatozoa of the salamander and triton, which from their large size are well fitted for study: first, a long head; second, an elliptical part connecting it with, third, the filiform body; fourth, a very fine, long thread, which is united to the body by, fifth, a homogeneous membrane. The thread and membrane are in constant motion during life, and apparently not easily understood. Mr. Gibbes finds that the head is of a different chemical nature from the other parts, for while they are stained by hæmatoxylin the head is not, or but very slightly. If aniline blue is then applied the head is affected by it. Mammalian spermatozoa are less satisfactory objects, but the author has found the filament in those of the horse, dog, bull, cat, rabbit, and guinea-pig. He has seen it better in the spermatozoa of the horse than in those of the other mammals. Mr. Gibbes draws the following conclusions:—

"(1.) That the head of the spermatozoa is inclosed in a sheath, which is a continuation of the membrane which surrounds the filament and connects it to the body, acting, in fact, the part of a mesentery.

"(2.) That the substance of the head is quite distinct in its composition from the elliptical structure, the filament, and the long body, and that it is readily acted upon by alkalis: these reagents have no effect, however, on the other part, excepting the membranous sheath.

"(3.) That this elliptical structure has its analogue in the mammalian spermatozoon: in the one case the head is drawn out as a long, pointed process; in the other it is of a globular form, and surrounds the elliptical structure.

"(4.) That the motive power lies, in a great measure, in the filament and the membrane attaching it to the body."

THE NATURE OF THE CELLS OF THE GASTRIC GLANDS.

Histologists are not quite agreed on some points of the arrangement of the cells of the peptic glands, but it is admitted that these glands contain cells of two kinds; those known as central or chief cells (Haupt-

zellen), bounding the cavity of the gland, closely resemble columnar or cubical epithelial elements; the others, peptic cells or parietal cells (Belegzellen), are more opaque, but have a more distinct nucleus. Some authorities have it that these cells bound the canal for a part of its length, and at the deepest part of the tube are situated outside of the former kind. Klein denies that they are ever inside. Dr. Ludwig Edinger² is inclined to believe, from a number of observations and experiments, that there is but one kind of cell, and that the difference of appearance depends on the degree of activity; that the central cells when full of ferment increase in size, and become what we call peptic cells. He bases his opinion on the following reasons, which certainly seem to have weight:—

"(1.) The occurrence of transitional forms between the central and the parietal cells.

"(2.) The analogy that such a change presents to the process known to occur in other glands during secretion.

"(3.) The fact that many animals secreting pepsine have only parietal cells.

"(4.) The appearance of the stomach after fasting, in which only central cells are found.

"(5.) The fact that many conscientious investigators have brought forward strong reasons in favor of the central cells as pepsine formers, and many others in favor of the parietal cells."

Reports of Societies.

THE ANNUAL MEETING OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK, HELD AT ALBANY FEBRUARY 3, 4, AND 5, 1880.³

LATERAL CURVATURE OF THE SPINE.

DR. SAYRE, instead of reading a paper, gave a practical demonstration of his treatment of lateral curvature of the spine, by means of self-suspension and the plaster jacket, in the case of a patient furnished him by Dr. Van Derveer, of Albany; and he took this opportunity of presenting to the profession the latest improvements which he has devised in the method. In any instance where the projection is very marked at any one point, as the angle of the ribs, when the jacket has been worn for some time he removes the portion of the latter covering the part, by cutting out a triangular-shaped piece, with the base above, from the top of the jacket. The patient then being self-suspended, the jacket is wet for a few inches on each side of the opening, and a fresh plaster bandage roller is passed around the body once at the lower end of the V-shaped opening: after which it is carried but two or three inches beyond the opening, when it is reversed and carried the same distance on the other side. This is repeated until the opening is completely covered; the assistant in the mean while holding the bandage in position and rubbing it well in with his hands. A great improvement in the shape of the patient can usually be effected by this procedure.

Dr. J. Marion Sims read a paper on

THOMAS KEITH AND OVARIOTOMY.

Dr. Keith's first ovariectomy, he said, was done in 1862. His first hundred cases show a success that far

² Archiv für Mikroskopische Anatomie, Band xvii., Heft 2.

³ Concluded from page 206.

¹ The Quarterly Journal of Microscopical Science, October, 1879.

surpasses that of all other operators. In his third hundred he cured ninety-seven per cent., seventy-three of these constituting one continued series without a single death. At one time it was supposed by many that his success was due principally to the use of the actual cautery in severing the pedicle. Dr. Sims, wishing to investigate this matter for his own satisfaction, went to Edinburgh in July, 1879, to see some of Dr. Keith's operations, and he took this occasion to detail the latter's method of operating. Keith began the use of Lister's antiseptic method in March, 1877, and ever since then he has carried out Listerism in its minutest details; believing that it protects the patient against infection, even when the surgeon or his assistants have been attending infectious diseases. He employs ether instead of chloroform as an anæsthetic, and he has the carbolic-spray apparatus placed to the left of the patient's head, at a distance of eight or nine feet from the seat of operation. He is very systematic, and does nothing for show. He cuts quickly down to the peritoneum, removes the tumor with celerity, and closes up the wound rapidly also, but is very deliberate in tying bleeding vessels and cleaning out the peritoneal cavity. In the beginning of his career in 1862 he learned the importance of tying all bleeding vessels, and of leaving no bloody serum in the cavity.

Dr. Sims saw him operate on two cases, both of which were very bad, as the patients were old and feeble, and the tumors multilocular and with strong adhesions to parietes, omentum, and intestines. His trocar is one half inch in diameter. In one case he tied the adherent omentum in twelve sections with catgut ligatures, and cut it loose from the tumor. He then separated the latter from the intestines, removed it, and applied catgut ligatures to all bleeding points, whether on intestine, mesentery, or parietes. He must have applied forty catgut ligatures in each case that Dr. Sims saw. The pedicle he encircled with Baker Brown's cautery clamp, when he screwed the latter up tightly and cut it off with the actual cautery at a brown heat. He then cleared out the peritoneal cavity, and spent a long time in searching for and tying oozing points wherever he could find them. This Dr. Sims considers the peculiarity in which he differs from all other operators, as he goes on hunting and tying bleeding points long after any one else would close up the wound and leave the oozing to be controlled by rest and pressure. When he is satisfied that the peritoneal cavity is clean and dry, and not till then, he proceeds to close the external wound. He uses Spencer Wells's method of suture for the upper and lower angles of the wound, each suture having a needle at either end; while the middle sutures are passed with an awl-shaped needle, six inches in length, with an eye at the point, according to the method of Peaslee. The sutures were passed perpendicularly through the abdominal walls from a quarter to a third of an inch from the edge of the incision, and embracing the peritoneum. After the sutures had been passed, their middle portions were pulled asunder, one half toward each angle of the wound, and the peritoneal cavity was again searched for bleeding points. In one instance some were found and ligated. The deep sutures were then drawn tight and tied, and intermediate horse-hair sutures were introduced. In one of the cases the wound was dressed with thymol gauze, in the other with carbolic. In one a glass drainage-tube, seven inches long and a third of an inch in diameter, with per-

forations around the lower end, was passed through the lower angle of the external incision down to the bottom of the Douglass cul-de-sac before the sutures were tied, while in the other no drainage-tube was introduced. In one the operation lasted one hour and three minutes, and in the other an hour and twenty minutes. In one the size of the tumor was not mentioned, but in the other it weighed fifty-six pounds, of which twenty-two were solid. Before introducing the drainage-tube, Dr. Keith passed it through a small hole burnt in the centre of a thin sheet of india rubber about two feet square; three or four carbolized sponges, squeezed dry, were placed over the end of the tube, and the india-rubber sheeting was then folded over the sponges. By this arrangement the oozing of the bloody serum from the peritoneal cavity is absorbed by the sponges, and thus never soils the person or clothing of the patient. The sponges are examined from time to time, and squeezed over a graduated measure, so that the quantity of fluid can be noted. If no fluid passes out the tube is soon removed; but otherwise it is allowed to remain till all fluid ceases to pass, or until the latter becomes of a serous character and small in quantity.

Spencer Wells, Keith, and their followers, Dr. Sims continued, do not saturate their patients with opium after operations; they simply order twenty drops of laudanum or its equivalent by the rectum, to be repeated as required. The patient takes nothing but ice and a little brandy for the next thirty-six or forty-eight hours. After this light nourishment, such as beef tea and milk, is given for two or three days, and then, if flatus passes freely from the rectum, a more nutritious diet is ordered, unless something should arise to contraindicate it.

Dr. Sims said that Keith had used the clamp in his early operations, but later had adopted the Baker Brown method of using the cautery. If the pedicle was very slender, however, he transfixed it with two small malleable iron wires, one of which was tied on each side, and then, cutting the pedicle and wire off close, he dropped it in the peritoneal cavity. Listerism, he said, has killed the clamp, and even Spencer Wells, its great apostle, no longer uses it, while his pupils, Bantock and Thornton, have never employed anything but the carbolized silk ligature to secure the pedicle since they were installed as his successors at the Samaritan Hospital, in December, 1877. Dr. Sims said that he thought it mattered but little what was done with the pedicle, as its management did not greatly influence the result, but he thought that the worst thing that could be done with it was to clamp it. Listerism apart, he considered that Keith's extraordinary success depended more upon the care that he gave to ligating bleeding points and thoroughly cleaning out the peritoneal cavity than to any other one thing.

In closing he spoke of Keith in the following words: "Doubtless many of you would like to know what manner of man is Thomas Keith, who to-day occupies such a conspicuous place in the eyes of the medical world. Thomas Keith is fifty-two years old, tall and slender, six feet high, and slightly stoop-shouldered. He wears a full brown beard, and his fine, large head is covered with a profusion of long, silky, golden-ashen hair, which hangs down behind, gently curling over his coat collar. His forehead is broad and prominent; his nose is long and straight, slightly

aquiline, beautifully symmetrical, and strongly indicative of character. He has large, deep blue eyes, full of benevolence and gentleness, and he has what is one of the most attractive gifts of nature, whether to man or woman, a sweet, musical voice. He is as modest as a woman, and of a character altogether lovely. He is quick in action, and walks rapidly, as if he were trying to catch up with his great head, which is always in advance of his slender body. . . . He has such power of concentration that his mind is always intent upon the object of its pursuit, and he hastens to accomplish it. His whole soul is wrapped up in his work, and after he has performed a difficult operation he eats and sleep but little until he knows that his patient is out of all danger. I only wonder how a man of such high-strung, delicate nervous organization could so long have borne up under the great and anxious work that he has done. I regret to say that his health is not good, and that he is often compelled to leave his hard work and the rigorous climate of Edinburgh and seek recreation in the more congenial climate of the south of France. Let us all hope that the life of this great and good man may long be spared to shed new lustre upon our profession, for which he has already done so much."

Dr. Alexander Hutchins, of Brooklyn, read a paper on

FORCED ALIMENTATION.

It was the popular opinion, he said, that food should not be taken when the desire for food does not exist; and it was the object of the paper to hint at certain clinical facts that proved the contrary of this opinion, and pointed to forced alimentation as a therapeutic agent. The amount of needful food varied with a large variety of conditions, and in any special case it would not be difficult to discover whether the needful amount was taken and appropriated. The question in therapeutics was, How is it possible to cause the needful amount to be taken and appropriated? The opposition, therefore, might be physical or moral. The stomach might loathe or it might reject food. The necessity not being known to the individual, there might be no effort to take food; and, the necessity being known, the will power might be too weak to enforce it. The point was that there is a large variety of disordered conditions, unaccompanied by organic disease, to a very great extent the result of defective nutrition, where the amount of food taken is small in quantity, improper as to character, irregular as to time,—matters of long standing; which chronic habit of insufficient feeding can be overcome by a properly selected dietary, systematically arranged and rigidly enforced, with the result of a speedy restoration to health and vigor, which result cannot ordinarily be effected without this forced alimentation, and this without the intervention of drugs.

If there was one position that the physician could occupy as the skilled and competent adviser, he went on to say, it certainly was in the exercise of his experienced authority in constructing the details of a dietary, and insisting on implicit and unquestioning obedience thereto. No general advice would avail, and if any success was to be anticipated from the treatment the medical attendant must patiently and with calm assurance give his patient the most precise and intimate directions. Authority and persuasion must go hand in hand, in order that the result aimed at

may be accomplished. Moreover, the recognition of this principle of forced feeding as a therapeutic measure was a valuable adjunct in resisting certain influences of heredity, since the inheritors of certain constitutional taints were notoriously light and fickle feeders. The "weak stomach" complained of was also an uneducated stomach, but with latent possibilities that a cultivated discretion might call into vigorous exercise. This digestion, not stimulated by drugs, but exercised by materials that possess the elements of nutrition, could enforce a nutrition by which the malign hereditary influences might be set aside, and the maturing years be coincident with maturing powers of resistance that would be unknown to the period of development if ill trained and ill nourished.

Aside from all considerations of appetite, notwithstanding any weakness of will power, or the multiplied obstacles of repulsion, loathing, or seeming impossibilities, the first point was to get food of some kind into the stomach, in such quantities as may be possible at stated intervals, as a stern duty, either in fulfillment of an intelligent appreciation of the necessity or in submissive obedience to inflexible orders. The operation was at first strictly mechanical, and the physician should disregard the sense of taste with the same indifference that he would exercise in the administration of medicine in an emergency. In the selection, food that required mastication was to be avoided, and that without special flavor, which can be swallowed by a single effort, chosen. As a second consideration, solids and semi-solids had the preference over liquid foods. These were not only better borne than liquids, but had the effect of arousing very rapidly the special functions of the stomach; and it was to be borne in mind that the effort was not to assist a weak digestion, but to habituate the stomach to the presence of food, and therewith to provoke its activity. If there was one direction to be followed on forced feeding that was essential above all others, it was that this feeding should be conducted at regular intervals (the frequency to be regulated by the quantity taken), stretching over a long period of each day. As a matter of clinical observation, it had been found that this feeding was best practiced eighteen hours out of the twenty-four. As a rule, also, it was to be commenced before the patient was out of bed in the morning,—the earlier the better. Insisting upon stated intervals, unvarying as the clock, was of paramount importance; and this admitted of no concession to a weakened will, while it encouraged a physical habit.

In the condition referred to the nutrition was suspended, and not degraded, and the stomach was not functionally disordered, but torpid. Hence, the nitrogenized foods were inappropriate in the early stages of forced feeding; the inactivity of the entire digestive apparatus rendering it in a condition unfit to digest and appropriate them. In general the coarser farinaceous foods fulfilled the indications of bulk and an excess of refuse material stimulating the alimentary canal and its adjuncts throughout its entire length. The quantity was to be small at the outset, and the free use of water was to be insisted on as a requisite to success in the method; the latter being of great service in promoting absorption, in encouraging the action of the kidneys, in softening the dejecta, and in setting free the action of all the emunctories. Of course, these forcible measures for subverting a dys-

crasia and substituting therefor a normal condition of animal life were to be synchronous with submission to all those conditions which are justly recognized as influencing free animal action, such as regular evacuations, abundant fresh air, judicious exercise, and cheerful occupation. There was no class of invalids to whom mere general advice was more worthless than that here described, and certainly none who made more persistent demands upon, and were more harassing to, their medical adviser. But if forced alimentation could, on the one hand, assist in the recovery from certain forms of chronic invalidism, and, on the other, avert the consequences and inroads of more distinctive disease, the suggestion of this therapeutic measure might perhaps lengthen the list of curable disorders.

Dr. F. R. Sturgis, of New York, read a paper on

SO-CALLED GALLOPING SYPHILIS.

In it the writer calls attention, under the name of galloping syphilis, to those cases of rapid and malignant disease where the deep and severe ulcerations occur a few months after the initial lesion, and where the early manifestations are either slight or else entirely absent. He assigns the continuous effects of alcoholic poisoning, old age, mental depression, bad hygiene, and scrofula as among the principal causes in determining the condition in syphilis. It is nearly always associated with cachexia.

He gave the history of two interesting cases from Charity Hospital on Blackwell's Island, where ulcerative syphilis came on in each instance two months after the appearance of the initial lesion; in the first case being preceded by an erythema, and in the second by none. The author then went on to speak of the treatment, insisting on the combined use of mercury and iodide of potassium, and pushing both remedies to the utmost limit that the patient will safely bear without the development of toxicological symptoms. In cases where iodide of potassium is not tolerated, he recommends the internal use of tincture of iodine. He also lays stress, in conclusion, upon the use of tonics and a nutritious diet in such cases.

A paper on

THE PHYSIOLOGY OF OPIUM POISONING,

by Dr. Nivison, of Burdett, was read by title. Notwithstanding the fact that opium is so extensively used, he expresses the conviction that there is still lacking in the profession an agreement of opinion in respect to its therapeutic value and its physiological action, as well as in regard to the physiological action of the various agencies used as antidotes for it. The following points concerning opium poisoning, he says, are tolerably well established.

I. Opium destroys life mainly by suspending respiration.

II. It ultimately paralyzes the heart and circulatory apparatus.

III. All parts of the organism suffer, but not to the extent of the direct destruction of life.

But nothing short of a physiological exposition of the phenomena of opium poisoning will indicate the best methods of counteracting them. In order to study the subject intelligently, the effects of small doses should first be noted, and the writer states that their first appreciable effect is to stimulate the gray matter of the brain and increase its blood supply. In

consequence, nerve force is rapidly generated, which in its distribution quickens every function. By this activity the brain is soon exhausted, and sleep follows. A larger dose produces cerebral congestion and partial suspension of function, and a still larger one paralyzes the cerebral vessels, and thus causes blood stasis and coma. The coma of opium, he goes on to say, is usually more profound than that of apoplexy, on account of the special affinity of the drug for the respiratory centres. But respiration is also endangered from the action of the poison on the peripheral extremities of the vagus in the lungs; so that carbonic acid fails to produce the normal respiratory excitation. There is, however, still another danger to respiration. Ordinarily, when the vagus is paralyzed or divided, the incident impression needful for reflex respiration may come from almost any nerves of general sensibility; but opium paralyzes these also, so that there is no channel through which the necessary excitation can reach the centre, and the function therefore ceases.

Opium in poisonous doses, he continues, produces decided effects also upon the spinal cord. The production of tetanic convulsions is infrequent, but erotic phenomena showing disturbance of the genito-spinal centre are not uncommon. The contraction of the pupil is probably largely due to paralysis of the cilio-spinal centre in the upper portion of the cord; while the vaso-motor paralysis is principally due to the action of the poison on the vaso-motor centres in the cord. The influence of opium poisoning on the innervation of the heart is next considered, and the conclusion is reached that if the dose is large enough all the sources of the heart's nervous supply are ultimately paralyzed, although the heart continues to beat for a time after respiration ceases. The limits of the paper forbid the examination of the effects of the poison on the inherent contractility of the two classes of muscular fibres; though this, he says, constitutes an important factor in the suspension of respiration and the heart's action. For the same reason the effects of the poison on the glandular system are passed by, though they sustain an intimate relation to the elimination of the former.

Some agencies which physiologically antagonize the poisonous effects of opium are then noticed. Many diseases undoubtedly sustain this relation, so that when patients are suffering from them doses of opium which would ordinarily be poisonous can be taken with impunity. Among these may be classed nearly all those in which cerebral anæmia enters as a factor, and in these diseases, the writer says, opium brings to the brain just the amount of blood needful for the performance of its functions. In this connection the sustaining effect of the drug and the large doses borne in post-partum hæmorrhage are referred to. In other diseases, however, in which there is supposed to be cerebral hyperæmia, there is equal tolerance of opium. Cerebro-spinal meningitis is cited as an example of this, and a case is related in which very large doses were taken for many successive days; it being, in fact, the only remedy that seemed to have any control over the disease. Either the disease or the opium alone, he says, would have killed the patient — child — by causing congestion of the cerebral vessels; but acting simultaneously they neutralized each other, apparently, and thus an equilibrium of circulation and innervation was secured. This is believed

to be an illustration of direct antagonism. Again, many painful affections, such as dysentery, peritonitis, cancer, the passage of biliary and renal calculi, colic, strangulated hernia, etc., neutralize the lethal effects of opium, and in these it is thought that the pain produces the needed excitation to supply the afferent impression to the respiratory centres, and thus counteracts the paralyzing effects of opium on respiration. Electricity, cold, and flagellation operate in the same way, and if kept up by continued excitation maintain the respiratory function. Some cerebral diseases, attended with mental derangement, also counteract what would be fatal doses of opium in the normal state of the organism, and two illustrative cases are related.

The influence of certain drugs which antagonize lethal doses of opium is next noticed. Belladonna is the most prominent of these, and it is considered that the two poisons make a counter-impression on the nerve centres, and thus antagonize each other. Opium paralyzes respiration, belladonna stimulates it; opium paralyzes the heart, belladonna keeps it in action; opium dilates the cerebral vessels, belladonna causes them to contract. When opium paralyzes the stomach and emetics will not operate, belladonna will often excite the proper nerve influence and cause them to act. The antagonizing effects of the cinchona alkaloids are then spoken of. They maintain the integrity of the inter-cranial circulation, and thus tend to counteract the effects of opium on the respiration. A case is given in which a child was poisoned with laudanum. Other remedies were used for two hours very industriously, without effect; but soon after the administration of quinine, the symptoms improved, the respiration becoming more frequent, and convalescence soon followed. In conclusion, the writer says that the antidotes to opium poisoning are physiological, not chemical, and consist mainly of such means as make counter-impressions on the nervous system, and especially on the respiratory centres.

Dr. St. John Roosa read a paper on

THE EVIL CONSEQUENCES OF A NEGLECTED COLD IN THE HEAD,

in which the following views were expressed as to the importance of this subject. A large proportion of the cases of incurable deafness and of chronic conjunctival and lachrymal disease were due to frequent attacks of coryza. Children of feeble constitution were particularly subject to this affliction. They were not treated at all during its progress, even the physician, if called in, sometimes thinking it a matter of no account; yet frequent attacks always led to thickening of the mucous membrane, with all its evil results. Children could not be hardened, and they should be taught the dangerous consequences of improper exposure. Each physician should be the medical guide of the families that he attends, and not be likened to a fire-extinguisher, to be sent for when the flames have broken out. The autobiography of many young persons suffering from chronic ophthalmic, aural, or pharyngeal disease would show that they had been improperly nourished, and hence were subject to frequent attacks of cold in the head, which finally resulted in a condition which the specialist was obliged to consider incurable. The local means for the relief of coryza were ample, namely, confinement to well-warmed rooms,

and the use of diaphoretics, tonics, local douches, baths, narcotics, etc. The general means consisted in a care of the general health, with forced alimentation, if necessary. The whole medical profession was now awakened to the necessity of general hygienic care. Memphis, if properly sewered, would not probably again suffer from yellow fever; but there were dangers to the public health as great as those from such epidemics, in the neglect of individual hygiene.

Dr. John C. Peters presented the abstract of a paper on

THE PREVENTION OF CERTAIN ZYMOTIC DISEASES,

especially scarlet fever, with incidental allusions to the counter-action of measles, whooping-cough, and diphtheria. Scarlet fever, he claimed, was a very old disease, for Robertson correctly said that a large portion of the plague of Athens, B. C. 431, was nothing more nor less than a severe outbreak of malignant scarlet fever. This, with other diseases that were prevalent, was immensely intensified by the great filth and overcrowding in the city, and the fact that numberless unburied dead were left lying in the streets, and in and about the fountains, to which the patients had crawled during life. The same occurred in the siege of Thebes, in the first century of the Christian era, and Caspar Morris had well said that no one could furnish a more accurate description in the same number of words than Seneca did in speaking of this epidemic in one of his tragedies. Evagrius described an epidemic of scarlet fever, with sore throat, in Rome, A. D. 540. Then all traces of it were lost during the Dark Ages, up to the invention of printing, when it reappeared in medical literature during the great Spanish epidemics of 1500. The filth of the Spanish cities in those times exceeded all belief, and up to 1760, just one hundred and twenty years ago, there was no such thing as a privy in all Madrid; it being customary to throw all the ordure out of the windows into the streets and alleys at night, from which it was removed by scavengers the next day. Washing the whole body with urine (and drinking some of it, also) was regarded as a specific against pestilential disease; the individual who thus defiled himself little thinking that urine, containing renal and vesical epithelium, was one of the most certain propagators of scarlatina and other similar affections.

After speaking of the history of scarlet fever in England, Dr. Peters went on to describe the best means of preventing the spread of the disease as it now occurs in the United States. The scarlet-fever patient, he said, should of course be isolated in an upper room of the house. The treatment should be commenced, if possible, with a warm bath, to which good vinegar has been added, as this is one of the best of the domestic disinfectants; and the hair especially should be thoroughly washed, for which purpose tar or carbolic soap might be used. The nurse should wear clean calico dresses, which could be easily washed, disinfected, or destroyed, and it was often advisable for her to take a preliminary bath also. Carpets, curtains, and upholstered chairs or sofas should be removed from the sick-room, and disinfectants, such as carbolic acid or iodoform, should be placed in every vessel or utensil in the apartment. A solution of sulphate of zinc or table salt, with or without a little chloride of lime, might also be sprinkled over the floor or brushed into the cracks between

the boards. Inunction with carbolized vaseline or other adipose substance should be carried out several times a day over the whole person of the patient, and especially the hairy scalp. In this way the bed and body clothing were disinfected, and the exhalations as well as the dead epithelium from the body were rendered innocuous. It was better to use old, clean rags, instead of pocket handkerchiefs, in the sick-room, and to burn them at once; but if the latter were insisted on, they should never be placed under pillows or in the nurse's pockets, but always put in a glazed bowl in which a little chloride of lime had been sprinkled. All the dishes and table implements used by the patient or nurse should first be steeped in a strong solution of common salt or cleansed in vinegar, and then thoroughly washed. Any bed or body clothing which might be removed should at once be placed in a tub containing a strong solution of salt or chloride of zinc, and then thrown down by the nurse into the yard, where they should undergo a second soaking before being washed.

When the patient was convalescent several tepid baths, with thorough soaping and lathering of the entire body from head to foot, should be insisted on, and a small amount of carbolized vaseline should be used, at least on the hair, as a kind of disinfectant pomade. Special pains should be taken to disinfect the urine, as well as the discharges from the stomach and bowels, from the first, as there was every reason to believe that it is highly infectious, and especially if it is albuminous, and so capable of rapid decomposition. The above precautions, with very little modification, might be applied to cases of measles, varioloid, and small-pox. In diphtheria and whooping-cough every particle of discharge from the nose, throat, and air-tubes should be disinfected, and it was also quite as necessary to disinfect the urine as the vomits or feces. When this hygienic treatment was properly carried out, it was rare to have a second case in the house, and a thing almost unheard of to have any of these infectious diseases conveyed to neighbors or the public in general. It was further recommended to burn a little sulphur, or to generate chlorine gas with the aid of manganese, from time to time in the cellar, basement, or lower hall, so that the whole house might be disinfected from below upward.

Dr. C. S. F. Gay read a paper on

REFRACTURE FOR THE CORRECTION OF DEFORMITY FROM THE MAL-UNION OF BONE.

In the outset he called attention to the importance of two factors entering into the subject which he thought had not been properly appreciated by surgeons: (1) the innocuous nature of refracture, and (2) the certainty and rapidity of the reparative process in a ruptured callus. Having answered in detail the four following objections urged against refracture, (1) that the muscles, which have become contracted and accustomed to their new relations, will not permit of extension and greater length of limb, even though tenotomy be performed; (2) that it would be followed by non-union; (3) that when trial is made to attempt to refracture a bone the latter will give way at some other point than at the callus; and (4) that the force necessary to rupture a callus is apt to inflict injury upon the muscles and excite inflammatory action, he went on to speak of the time beyond which it would be imprudent to attempt refracture, and expressed his

agreement with the opinion of Shay that "the only limit of time is the power to break the callus." He then gave the report of two cases; one of refracture of the tibia and fibula, at the junction of the middle and lower thirds, twelve months from the date of fracture, with correction of deformity; and the other of refracture of the shaft of the femur, at the junction of the upper and middle thirds, five and a half months after fracture, with entire relief of deformity. In conclusion, the writer stated that we ought to expect more notable relief of deformity to follow refracture of the neck of the femur than of any other portion of this bone, and that he believed that many of those individuals seen on every hand in the streets, whom we are accustomed to style cripples, suffer from preventable and curable deformity.

Among the other papers presented at the session were the following: The Relation between Imperfect Action of the Ocular Muscles and Functional Nervous Disorders, by Dr. George F. Stearns, of Albany; Rectal Alimentation, by Dr. Potter, of Batavia; Extracting a Splinter of Wood from the Cornea, by Dr. L. Webster, of New York; The Removal of Foreign Bodies from the Eye (with four cases), by Dr. C. S. Bull, of New York; Caries of the Ankle-Joint, by V. P. Gilney, of New York; Cystorrhagia, by Dr. J. W. S. Gouley, of New York; Perityphlitis, by Dr. C. W. Wey, of Elmira; Typhlitis and Perityphlitis, by Dr. A. H. Van Derveer, of Albany; The Management of Eczema, by Dr. L. D. Bulkley, of New York; A New Way of Treating Deformities of the Nose, by Dr. R. F. Weir, of New York; Vivisection, by Dr. John C. Dalton, of New York; Colles's Fracture, by Dr. E. H. Moore, of Rochester; Sub-Periosteal Resection of the Humerus, by Dr. George F. Shrady, of New York; Mercurials in Congestion and Sub-Acute Inflammation of the Stomach and Duodenum, by Dr. E. N. Chapman, of Brooklyn; Vascular Nævus, by Dr. G. H. Fox, of New York; and The Lunacy Question, by Dr. A. McL. Hamilton, of New York.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.¹

T. M. ROTCH, M. D., SECRETARY.

NEUROTOMY.

Dr. WILLIAMS referred to the paper on Neurotomy of the Optic and Ciliary Nerves, read by him at a recent meeting. He had to-day seen a case on which he operated two weeks since, where the symptoms of ciliary irritation had been at once relieved. He had also seen, since the reading of his paper, four of the cases therein referred to, operated on at different times since September last. All of these continued free from any bad symptoms in the eye where the enervation had been done, and the other eye had recovered from the threatening of sympathetic inflammation which existed at the time of the operation.

The *Annales d'Oculistique* for November and December, 1879, contains an article by Dr. Warlomont, of Brussels, giving an interesting history of this enervation (by simultaneous section of the optic and ciliary nerves), first done by Boucheron, of Paris, in 1876, and the following year by Schoeler, at Berlin, and referring to thirty-six cases in which the operation had up to that time been performed by European oculists.

¹ Continued from page 180.

OVARIAN CYSTS.

DR. JOHN HOMANS showed specimens of ovarian tumors from patients operated upon during the past week. The first was a sarcomatous tumor of the ovary, the size of an infant's kidney, from a case of double ovariectomy in a woman fifty-one years old. The patient was first seen by Dr. Homans in November, 1879. Her case was thought to be one of ascites, but the diagnosis was not positively determined. Tapping was done at the first visit, in consultation with Dr. Morison, of Quincy, and twenty-two pounds of clear ascitic fluid removed. Considerable abdominal pain and soreness followed the tapping, but after a few days the patient improved much in health and strength. In January, 1880, she had refilled considerably, and Dr. Homans suggested an exploratory incision to be done antiseptically. He explained to the patient that this was simply a freer mode of tapping, and if there were an ovarian cyst it could be removed, and if not the fluid could be much more completely and thoroughly removed from the abdominal cavity by careful sponging than by simply letting what would run off through a trocar. Dr. Homans felt encouraged to do this for another reason: in a somewhat similar case he had removed ascitic fluid by an abdominal incision, and by baling out with sponges, and the fluid had never re-accumulated after the patient's recovery, though she had a sarcomatous tumor involving both ovaries and the uterus, which was not meddled with, as it seemed impossible to remove it with safety. The patient had had her breast removed for cancer seven years before, but there had been no recurrence, and she seemed in a fair state of health, though considerably emaciated. The operation was done antiseptically at Carney Hospital on February 4th. Twenty pounds of ascitic fluid and both ovaries, enlarged by sarcomatous growth, were removed. Some of the glands in the anterior sacral region and portions of the pelvic peritoneum were more or less studded with similar growths. The patient is making an excellent recovery, and it is to be hoped that the fluid will not reaccumulate.

The second specimen was a multilocular cyst of the right ovary without adhesions, removed the day before from a patient thirty-eight years old. The tumor and its contents weighed twenty-five pounds. The patient is doing excellently.

CLUB FOOT AND HAND.

DR. E. H. BRADFORD exhibited casts of a rather unusual deformity, a club hand and foot in the same patient, a child. They were said to be congenital, but had all the characteristics of the acquired form. The child since the operation, which was the ordinary tenotomy for club-foot, was able to use the fingers, but on raising the metacarpus the fingers doubled upon themselves. The result, which was shown by the casts to be a very good one, was accomplished after four weeks, the treatment after the tenotomy being simply the plaster-of-Paris bandage.

HERNIOTOMY.

DR. C. B. PORTER exhibited a patient on whom he had performed the operation of herniotomy. The patient had entered the hospital six hours after the symptoms of strangulation had begun; vomiting was frequent, and after aspiration efforts at taxis under ether had failed. The constriction was at the internal ring

and the hernia was of the congenital variety. There was atrophy of the testicle on that side.

The operation was performed with Lister's antiseptic precautions. The temperature went above 99.6° F. The dressing was changed only three times, and was omitted on the twelfth day, the patient sitting up on the nineteenth day. There was at no time any discharge of pus.

After the intestine was returned, an operation for the radical cure was performed by a new method. A piece of the sac two and a half by three inches long was divided from its attachment, except at the upper part near the ring, where a pedicle one and a half inches wide was left to afford nourishment. This piece was then folded again and again upon itself and sewed into the ring by carbolized catgut sutures.

Up to this time, eleven weeks after the operation, there has been no tendency of the hernia to return, and there is no impulse to be felt in the ring on coughing.

PROLAPSED FUNIS.

DR. GARLAND exhibited an apparatus devised by his father, Dr. G. W. Garland, of Lawrence, for replacing a prolapsed funis. The instrument consists of a long pair of thin duck-bill forceps, which are curved like the blade of ordinary obstetric forceps. Supposing a funis to prolapse, Dr. Garland does not grasp the part itself in his forceps, because by so doing he would stop the circulation of the child and be apt to injure the tender membranes. To obviate these troubles he folds a small piece of cotton cloth, about two inches long by one inch wide, around the funis, and then seizes the ends of the cloth in the forceps. The funis is thus hung loosely in the fold of the cloth and must go wherever the latter does. The thinness and curve of the forceps allow of their ready passage around the head, and the funis may thus be carried as high as desirable. In removing the forceps the bit of cloth will of course remain *in situ*, to be discharged later when the funis is delivered.

FEBRUARY 28, 1880. DR. JAMES C. WHITE, permanent chairman, presided.

TYPHOID FEVER.

DR. CHARLES F. FOLSON read a paper entitled Suggestions as to the Causes of Typhoid Fever, in which he said:—

During the latter part of last summer my attention was called to several cases of typhoid fever in one house, so sudden in their appearance that poisoning had been suspected to be the real nature of the disease, although the attending physician was quite sure of his diagnosis of enteric fever.

Mr. — was quite ill with severe diarrhoea in August, but the true nature of his illness was not made out until September 7th, when he took to his bed and sent for his physician. His dejections, several a day, for three weeks, had been cast into the privy-vault adjoining his house. In the next two weeks there were three rain-storms, although the season, generally speaking, was a dry one. Between September 30th and October 12th, every individual who drank the water from the family well, comprising the wife and seven children of the sick man, became ill with typhoid fever.

The well was one hundred feet distant from the privy, about sixteen feet deep, not containing a large supply of water, and situated in a gravelly subsoil cov-

ered with light loam. The privy-vault, not tight, was emptied once a year. Great suddenness of an outbreak of disease naturally suggests fault with the food or water. The food and milk were found above suspicion. The well-water would have been considered by most persons at a safe distance from sources of contamination. Throughout the summer it was perfectly clean and free from any unusual taste. Upon chemical examination it was found to contain in parts per million: ammonia, 0.01; albuminoid ammonia, 0.13; total solids, 233.00; chlorine, 33.00; nitrates, 0; considerable blackening on ignition. Chemically speaking, the water was as good as that often supplied by Lake Cochituate and Fresh Pond, and far superior to the Mystic, at times. The trifling amount of ammonia and absence of nitrates suggested the thought that the excessive amount of albuminoid ammonia might be due to vegetable organic matter, and the amount of chlorine was no greater than is often found in wells so near the salt water as this one happened to be. In order to be sure upon this point, I took some water from the same drainage area, five hundred feet distant, and found it, upon examination, to contain the same amount of ammonia with the same absence of nitrates as the first specimen. The albuminoid ammonia, however, was only 0.7 instead of 0.13, as above, the chlorine 24.0 instead of 33.0, and the total solids 153 instead of 203. This comparison of the suspected well with the normal water seems to me the only satisfactory one where there is doubt, and in this case made the probability of infection of the well from the privy almost a certainty.

I then had the privy-vault emptied, and two bushels of salt thrown in, with a large quantity of water. Subsequent examinations every three days, from October 26th to December 3d, showed a steady increase in the amount of chlorine found in the well up to forty-four parts per million on November 5th, and then a steady decline to twenty-nine parts, or four parts less than were found in the very first examination of the suspected well, and only five parts more than in the normal water of the district.

Such crucial tests as this have so often been applied that there can be no longer a doubt that the discharges from typhoid-fever patients contain a specific poison in some form, which, in the vast number of cases, produces the same disease in the persons taking the so-called germ into their systems under circumstances favorable to its development. A large number of cases might be cited to show that this peculiar specific poison is conveyed also in air and gases, notably sewer-gas and in the air exhaled from soil in which the dejections from typhoid-fever patients have been deposited, possibly from any organic matter decomposing under certain conditions.

Professor Frankland, of London, has shown that lithium placed in sewage and flowing through sewers, where the current is continuous and the liquid not agitated or stirred up, cannot be detected by spectroscopic examination in the sewer-gas. If, however, the sewage is splashed up the lithium is readily detected by the same method, and any process which drives sewer-gas into houses also carries the lithium with it. The same fact is of course true of the specific particles which produce typhoid fever or other diseases.

The air in the soil, too, even very many feet deep, is subject to constant variations of pressure, etc., and is always changing. The amount of carbonic acid formed by decomposition going on in the earth and driven into

the air, together with other results of putrefaction and decay, is at the warm seasons of the year enormous. This chemical and physical change goes on most rapidly in those portions of the soil which are alternately wet and dry from changes in the level of the soil-water, and by many leading authorities is considered an essential factor in the production of enteric fever.

It has been clearly shown that this specific poison from the discharges of persons sick with typhoid fever, when kept away from exposure to the air, maintains its potency to produce the parent disease for some time, and that it may be conveyed long distances in water or milk. How far it multiplies and under what circumstances, outside of the human body, of course we have no means yet of positively stating. It is destructible readily upon free exposure to pure air, as was markedly shown, for instance, in the recent great epidemic at Croydon, England. Fourteen hundred cases occurred in that city, distributed chiefly by sewer-gas, and a great portion of the dejections from them passed into the sewers without disinfection. The sewage from these sewers was spread over an irrigation farm, to the emanations from which large numbers of laborers and tenants near by were exposed. The water of the surface wells in that vicinity, really the purified sewer-contents, constituted the almost sole supply for domestic purposes for a large number of people, and in no case was the fever propagated in that part of Croydon. I have quoted in the reports of the State Board of Health the only two cases, so far as I know, which the English Rivers Pollution Commission have been able to find as a basis for their opinion of the extreme indestructibility of the so-called germ of typhoid fever. These two cases are an outbreak of typhoid fever in a prison of Dublin, Ireland, alleged by Dr. Mapother to have been due to drinking the water of the river Liffey, after it had flowed twenty-five miles from a barrack, where it was polluted with the dejections of soldiers having the disease, and the epidemic in a village of Switzerland, where the excrement of a single man sick with typhoid passed into a brook, flowed a mile through a hill of gravel, and then was supposed to have polluted a large well so as to have infected several hundred people. It is but fair to say that evidence collected subsequent to the reports of these cases throws very great doubts upon the alleged causes of the fever, that there were other local means of spreading the disease, and that I am now inclined not to regard them as fully authenticated, inasmuch as repeated investigations have not brought to light corroborative evidence of their soundness, and have led me rather to the opposite opinion.

The specific poison of typhoid fever is readily destroyed by measures which utterly fail to kill many of the bacteria spores found in the air, for instance, boiling, and, in my judgment, although perhaps that point is not so well determined, by exposure to certain concentrated gases, like sulphurous acid and other efficient disinfectants.

The personal contagion of typhoid fever is admitted when patients are crowded together. I have seen repeated cases which have convinced me of that fact, but I will detain you only a moment on this point to quote Mr. Simon, who says, "Typhus and typhoid fevers, which amid overcrowding and non-ventilation and refuse odors and foul water supply would be the most spreading of pestilences, will, in thoroughly clean atmospheres and with thoroughly clean water supply, be

so restricted in their infectiveness that typhoid will scarcely be recognized as contagious, nor even typhus extend beyond limits which admit of being narrowly defined." Virchow also supports this position.

In the Croydon epidemic, just referred to, the presence of sewer-gas was detected in several sleeping-rooms where typhoid occurred by the noise it made in escaping through small holes in the pipes, and it could not be noticed at any time in them by the sense of smell. Admitting the existence of a specific poison which may be so entirely eliminated from its filthy surroundings as not to lead to even a suspicion of its filth origin in the human intestine and its discharge with human excrement, the question remains, Is filth alone ever, under any circumstances or by any modifications, capable of producing typhoid fever independently of any matter derived from a previous case of the disease? At the start we must acknowledge that in discussing this problem there is an *x*, an unknown factor, of which we know as little as we know of the so-called "germ" of any disease,—that is, we do not even yet know certainly that it exists. If we ignore this unknown factor, it must be admitted that the negative evidence enormously preponderates over the positive facts which tend to show that filth, independently of a specific poison, produces typhoid fever. Since I commenced investigating this question I have been amazed at the immense amounts of urine and excrement—oxidized, incompletely oxidized, and as they come from the bladder and intestines—that are consumed in drinking water and inhaled at the rate of nine thousand litres of contaminated air a day, and this for years, by young, old, and middle-aged persons, without any disease resulting that may be attributed to filth. I do not mean to deny the danger of filth. Especially filth decomposing without the free access of air constitutes, in my mind, one of the most important secondary factors of disease,—one, too, which may become so essential a factor in some diseases as to absolutely be the one without which, in an aggravated form, the disease cannot exist, as, for example, in cholera, plague, and yellow fever. I do not think, though, that a risk, however great, should be declared a certainty, nor that the influence of filth in causing disease should be overstated, although not seldom an isolated filth-sodden well or cess-pool, without any traceable connection with a case of typhoid fever, seems to be the essential cause of that disease in persons exposed to their influence. Typhoid fever is by no means a disease of the filthiest towns or of the filthiest parts of towns. Where it seems to originate in filth, the filth is often, at least, so lost sight of that it can be recognized only by an expert. It is found in the typical New England village, where people take especial pains to keep their houses clean, to empty their privy-vaults twice a year, to put their wells at what is commonly thought to be a safe distance from sources of pollution. The well-water, on chemical examination, shows a trace simply of impurity, or only justifies the assertion that there is a suspicion of its pollution; the emanations from the soil, if dangerous, are not attended with any warning stinks, but there is a certain contamination of the earth with excrement, and a very possible admixture of a trifling amount of fecal matter in the well. One case of typhoid fever appears without a previous case having been known before in the vicinity; then another a quarter of a mile distant; then another; and then, as in the case of Saugus, reported in the ninth

Report of the State Board of Health, seventeen cases appear in a population of one thousand people. The cases are widely separated, they are all mild, none prove fatal, and there is rarely more than one in a single house. There does not appear a chance for a community of cause, after the strictest investigation, for the single cases, or for the small groups of cases occasionally appearing together. They are scattered both over a large territory and over a considerable space of time, mostly in August and September, and they very seldom cause death, except when a patient thought pretty comfortable suddenly dies of intestinal hemorrhage.

Attended with this mild fever, there are cases where the temperature remains high for only a few days and the illness lasts hardly over a week. In moderately malarious regions, as Virchow observes, it is not infrequently true that it is extremely difficult to make a correct diagnosis of the more obscure and protracted of them, and to say definitely whether the illness is typhoid fever or pure malarial fever. Very many such are observed, especially in the river-valleys and near natural or artificial ponds, notably where large areas of their exposed beds serve to exhale into the atmosphere the products of vegetable decomposition. I have looked up a number of cases in various parts of the State, and am convinced that nearly all at least are pure or modified typhoid, so far as my observations have gone. Physicians within whose experience they come more or less every year are still at variance as to their character, that is, whether they belong to true typhoid or not; and there is the same difference of opinion whether their origin is in the very small quantities of filth proper with which they are associated, or whether they are due to vegetable decay chiefly.

In such cases as those just quoted, there seems to be abundant evidence from our country towns that filth under peculiar and unknown modifications, plus the unknown factor, is sufficient, without the so-called specific germ from a previous case, to cause typhoid. The appearance in the typhoid of many mild attacks of fever of short duration suggests the suspicion that all are cases of filth-poisoning, of greater or less degree of intensity, or that the filth in the various individuals has more or less of the unknown modification necessary to produce enteric fever, or is met by a greater or less predisposition to the disease. Naturally it is not possible to obtain such evidence in cities.

I often hear it stated that such and such a thing cannot be the cause of a certain series of cases of typhoid fever, because others more exposed did not contract the disease; and this query suggests an important factor in the causation of the fever which is often overlooked, namely, the predisposition of certain individuals or classes, the most potent causes of which are the underfeeding, want of cleanness, lack of pure air, water, etc., incident to poverty. Of 1087 cases of typhoid fever recently investigated in Berlin, the results of which were published by Dr. Skrzeczka, the ratio of the sick per 1000 inhabitants increased from 0.83 in the basement to .84 on the ground floor, .96 and .95 in the first and second stories, 1.1 in the third story, and 1.4 in the fourth and fifth stories. In a recent number of the *Berliner städtisches Jahrbuch* similar statistics are given for the 939 deaths from typhoid fever reported in the year 1875, excluding those where the story of the house was not stated in the death returns; the figures are as follows: 0.89, 0.91, 0.95, 0.90, 1.03, 1.71. These calculations, in both cases,

were based on the census of 1874, and the last figure given, 1.74, as the rate per 1000 on the fourth and higher stories, is probably a little too high. But still, the figures are very striking.

All of course had the same water supply. Those living at the top of the building had to carry the water for domestic purposes the farthest, and had the least facilities for cleanliness. They were, too, the poorest, because the highest rooms were the cheapest. The remaining probable causes of the fever were certainly no worse for them than for the others, and on the more prevalent German theory, that the ground is the chief source of the cause of typhoid fever, they were the best off, and yet they had the greatest percentage of enteric fever.

A telluric influence, something in the chemico-physical history of the earth, which we do not yet understand, apparently governs the relative prevalence of this as well as other diseases in different years and at different periods of time. In the minds of many careful observers, this constitutes the chief factor, with perhaps antinatal decay of vegetable matter.

Typhoid fever is diminished by the introduction of pure water supplies, and the cases which still occur where pure water is introduced have a lower rate of mortality than previously. Efficient sewerage also has so very favorable an influence on its prevalence as to practically banish the disease, if coincident with pure water supplies, and in cities in first-rate sanitary condition typhoid fever becomes a disease of the apparently cleaner, but less well-drained, outlying districts. Defective sewerage, on the contrary, so tends to favor the spread of typhoid that we may always predict a progressive relative increase in its prevalence up to a certain point from the time that the sewers first become foul until they are made clean and self-flushing. This fact is so fully recognized in some European cities that the local sewers are provided with means for flushing and are flushed with clean water whenever there is an undue amount of typhoid. Enteric fever does not depend upon density of population, but it is prone to attack persons of deficient health from any cause, and the ill-fed. So far as my observations go, it is essentially a filth disease, in that its origin is always in decomposing organic matter, generally in what is filthiest of filth, human excrement.

It does not prevail most, however, in the filthiest towns, nor in the filthiest parts of towns, nor in the most stinking localities, nor necessarily in those years when stinks are most abundant or filth most accumulated, and in the sense of being an index of the degrees of filthiness of places, except where all the other conditions are exactly alike, unknown factors and all, it is very far from being a typical filth disease.

Commonly speaking enteric fever prevails more widely, other factors being equal, where excrement, decomposing without free access of air, contaminates water supplies or the air of dwellings or near them; and as those conditions obtain more in the country than in the cities, it is in the rural districts that it is most prevalent, but that law is by no means a constant one. So far as Massachusetts is concerned, impure water is the much more common source of infection; and in sewerage parts of our cities sewer-gas appears to me its almost only local cause, for the water supplies are usually excellent, and there are few vaults or cess-pools. Using the census of 1875 as the base for comparison, — not an accurate method for absolute rates,

but sufficient for our purpose, — it seems that for the ten years ending in 1878 typhoid fever had a decennial rate per 1000 in Hampden, the lowest of the Connecticut Valley counties, of 11.58; in Dukes and Nantucket of 11.14; while the other two Connecticut Valley counties of Franklin and Hampshire come next as 10.41 and 10.24; then Berkshire and Barnstable, the extreme western portions and the Cape, 8.80 and 8.21; Worcester, or the central part, 7.52; Bristol and Plymouth, situated next to the Cape, 6.59 and 6.53; Essex, 6.23; Middlesex, 5.79, has one half the extreme rate of Hampden, the greatest; Suffolk, 5.62; and finally Norfolk, 5.48.

There has been a steady decline in the disease during the ten years for the State at large, except that in 1872 and 1873 there was an increased prevalence. Suffolk County, however, does not show so great a decrease as the rest of the State; the total deaths in Massachusetts from that cause in 1869 being 1205, and 679 in 1878. If Suffolk County Boston, Chelsea, Revere, and Winthrop be compared with the rest of the State, it appears, therefore, that its typhoid fever record is an unfavorable one.

Taking Boston alone, it seems that the deaths from typhoid fever in the last ten years have been respectively, beginning with 1869, 138, 168, 176, 229, 243, 231, 200, 148, 157, 129, with an increase in population from about 260,000 to not far from 360,000. It is unfortunate that there are no statistics on record by which it is possible to ascertain the exact degree of prevalence in the various localities. It appears, however, that Dorchester, West Roxbury, and Brighton have comparatively little of the disease, and that it is most prevalent in East Boston, the North End, South Boston, the Church Street district, and large portions of the territory lying between the South Bay and the basin formed by Stony Brook and Muddy Brook. Boston contains nearly twenty-two per cent. of the population of Massachusetts. In 1869 the deaths from typhoid fever in Boston were 11.45 per cent. of the mortality from that cause for the whole State. In the succeeding nine years, respectively, 12.60, 15.77, 13.45, 17.32, 20.14, 18.88, 16.80, 19.29, 17.67. The average of the first five of these figures is 14.12, of the last five, 18.55; showing a difference of 4.43. While Boston contains nearly twenty-two per cent. of the population of the State, its proportion of the deaths from typhoid fever in the last five years has ranged from 16.80 per cent. to 20.14 per cent., the difference being very much less than is commonly supposed in its favor.

Although the typhoid rate in Boston is declining, it has not declined so much in the last ten years as in the State at large; enteric fever does prevail most in the sewerage portions of the city rather than in the rural parts; Norfolk County, with no sewerage towns, has a lower typhoid rate than Boston; the chief factor in originating typhoid fever, or in transporting it, or both, according to the theory which each one may hold upon that subject, is, in Boston, sewer-gas, and there are measures by which its prevalence may be diminished.

First, it is very much to be regretted that there is no thorough and scientific analysis of the death returns of the city.

Secondly, by the present construction and management of our sewers they are elongated cess-pools of a very dangerous kind, inasmuch as they serve to con-

nect with filthy districts houses which by themselves might be easily kept clean. The new intercepting sewer will remedy many of the evils incident to our present sewerage, but by no means all. Many sewers will need to be built anew, others to be reconstructed. This important work needs for its supervision and control the highest attainable skill and experience, and should be united with the intercepting sewerage system under the direction of the city engineer.

Whatever theory may be held with regard to the causation of typhoid fever, it must be admitted that its origin is so often in sewer-gas that we should protect our dwellings efficiently against any risk from it. The precautions to be observed are illustrated in the diagrams which I will now show [of water-closets and a system of house drainage].

DR. A. H. NICHOLS said that the question of the spontaneous origin of typhoid fever in the inhalation or ingestion of decomposing organic matter was rendered difficult of solution by the circumstance that there exist maladies induced by the absorption of a variety of recognizable noxious agents other than typhoid poison, in which the local lesions and the general symptoms bear a close resemblance to those of typhoid. Such manifestations occurring in a large city where typhoid is usually endemic cannot always be distinguished from those of typhoid fever. An instance of this form of error is afforded in the extensive epidemic which was termed typhoid fever, contracted at the musical festival in Zurich, in May, 1878, and said to have been produced by the consumption of putrid meat. Where, however, these ambiguous cases are observed in isolated localities where infectious diseases of any description are of the rarest occurrence, superior advantages are of course afforded for determining their specific character. Some such combination of conditions is met with at Rye Beach, New Hampshire, where in summer a large population of visitors is crowded into old farm-houses, originally constructed for the accommodation of single families, and where the arrangement of privies, sewerage, water supply, etc., is often such as to defy all sanitary rules. A large proportion of the wells are here exposed to the danger of contamination from organic matter proceeding from adjacent dung-hills, surface privies, and sink-spouts. In this region there prevails during the latter half of each year, when the water in the wells is at its lowest point, and the contaminating agent most abundant, a disease termed by the inhabitants fall fever, and by the local practitioners typhoid, but observed exclusively, so far as has yet been ascertained, in houses exposed to the insanitary conditions above described. The chief symptoms—the general course of the temperature and pulse, diarrhoea, meteorism, gurgling in the course of the colon, delirium, somnolency, etc.,—are almost identical with those of a typical case of typhoid. The invariable absence, however, of those more significant and pathognomonic signs, namely, the enlargement of the spleen and the characteristic roseola, coupled with the fact that the disease has almost uniformly a favorable termination, renders it extremely probable that we have here to do with instances of filth poisoning in which the local enteritis and intestinal glandular lesions as well as the clinical symptoms are not differentiated from those occurring in genuine typhoid. It is another significant circumstance in these cases that the severity of the symptoms is often found to be directly proportionate to the quantity of water consumed, and

that cattle, particularly horses, manifest a decided and similar susceptibility to its effects.

Caution should therefore be exercised in the abandonment of existing ideas as to the aetiology of the so-called zymotic diseases, and in the substitution of the theory of their *de novo* origin in filth, especially when this theory is supported solely by a class of cases of so doubtful a character as those here referred to.

DR. G. B. SHATTUCK said that in some of the Southern and Western States the "common continued fever" of the country presented most of the symptoms which we associate with typhoid fever, but in a much milder form. The absence of rose spots, however, and of marked splenic enlargement is common. The intestinal lesions found in fatal cases prove the disease to be typhoid fever. The same is supposed to be true of the mountain or typho-malarial fever of the Rocky Mountains. A paper by Dr. Hope in the Transactions of the Tennessee State Medical Society for 1878 and reports by Surgeon Woodward and Assistant Surgeon Hoff were quoted.¹

A case reported recently in Germany was quoted as tending to show that the typhoid poison might preserve its activity for so long a period as two years. Dr. Shattuck thought that country practitioners were more disposed to accept the *de novo* origin of the disease than their city brethren, owing to their being able to approximate more nearly to a certain exclusion of importation, but that the use of the term *de novo* was attended often with much vagueness, and that many of those employing the expression would accept neither the theory of spontaneous generation nor that of mere filth origin. In support of Dr. Folsom's view, that filth alone was not sufficient to cause the disease, Dr. Shattuck mentioned the extraordinarily filthy condition of many villages and towns in China, where typhoid fever is rare.

In answer to a question Dr. Shattuck said that the veal eaten at the festival in the province of Zurich was known to have come from a very sick calf, and that typhoid fever has been observed in calves.

MR. E. C. CLARKE, the engineer in charge of improved sewerage, said that he was sometimes asked by physicians, and very often by non-professional gentlemen, whether we shall do any good by this new sewer; and that he had answered that in certain localities, where the sewerage now causes the most nuisance, great good would be done. By next January the new pumping engine will be ready, and can be used with great benefit if the sewage is allowed to be discharged into Dorchester Bay for two years, until the arrangement for disposing of it at Moon Island are perfected, which will not, however, be before January, 1882. But even when this new system is completed we shall still have typhoid fever, for a large portion of the trouble comes from the individual houses being badly drained. Many of the street sewers are also in bad condition, so that although the intercepting sewer will do some good, and is the first step to be taken towards improving the health of the city, still we shall not have a good system of drainage until the house drains and street sewers are thoroughly renovated.—DR. WHITE asked if the reconstruction of the city sewers rested in the hands of the same board as that of the intercepting sewer.—DR. FOLSOM said that it did not.—DR. C. P. PUTNAM asked if the rain water would not flush and wash out the sewers, when they are once clean, now that the conductors

¹ American Journal of the Medical Sciences, January, 1880.

open directly into the drains. — MR. CLARKE said that many of the sewers were so defective that this would not be sufficient to keep them clean. Some of the old sewers were merely barrels fastened together; again, a four-foot sewer was at times found opening into an eighteen-inch pipe. He also spoke of the difficulty of getting at the sewers to see in what condition they were, citing as an instance a twelve-inch sewer, ten feet beneath the surface, running for a quarter of a mile without a man-hole to indicate where it was. — DR. LYMAN inquired if there was any record of the situation of the sewers. — MR. CLARKE said, only in those cases where the pipes had been laid during the last five or six years. — DR. G. B. SHATTUCK asked Dr. Folsom if he thought the inhabitants of Boston would be more likely to profit by the new system of sewers if the supervision of the entire system were put in charge of the city engineer. — DR. FOLSOM answered that he thought they would. — DR. WADSWORTH spoke of the stench caused by sewer-gas coming from the water conductors of a house where the conductors opened directly under the attic windows, and were connected with the sewer without any trap. — DR. C. D. HOMANS asked if this was not usually so. — DR. FOLSOM answered that it was in a large number of houses, but that it was possible to trap the conductors properly. — DR. J. C. WARREN spoke of the danger which may arise from the surface drainage of the surrounding houses, and instanced the analysis of water found in the fresh-air box of his house, reported by Professor Wood to be almost as bad as that from Mill River. — DR. WHITE asked for the reports of cases of typhoid fever occurring in Boston which had not been imported. — DR. BRADFORD mentioned a case in Park Square, and DR. C. P. PUTNAM a case in Newbury Street. — DR. ROWE spoke of the case of a nurse at the City Hospital who died of typhoid fever after taking care of a typhoid case, where she had not thoroughly carried out the precautions ordered for disinfecting the bed-pan. — DR. PORTER spoke of the case of a boy thirteen years of age who passed through an attack of typhoid fever of a mild form, and said that no assignable cause could be found after the most thorough investigation, excepting the possibility of his having been infected while excavating a tunnel on the new land; none of his playmates, however, had suffered in this way. — In answer to a question as to whether the men who worked in the sewers were made sick by it, MR. CLARKE said that he had not heard of any cases of typhoid, but that nausea and headache were of quite frequent occurrence. — DR. STEEDMAN spoke of some cases which came into the City Hospital at the time that the big sewer on Albany Street was being built. The men who had been working in the sewer showed symptoms which at first simulated typhoid fever, but did not run the typical course of typhoid; in that year, however, only two or three undoubted cases of typhoid came into the hospital, the cases seeming to be peculiarly mild throughout the year. — DR. FOLSOM said that it has been observed in Paris and London that it is not usually the workmen, who are continually in the sewers, who contract typhoid fever, but the inspectors, who are only occasionally exposed in this way. In answer to a question, Dr. Folsom said that by a law passed in 1877 all city boards of health in this State are authorized to make and enforce regulations with regard to house drainage. Some of the local boards are now moving in this matter.

Recent Literature.

A Dictionary of the German Terms used in Medicine.

By GEORGE R. CUTTER, M. D., Surgeon of the New York Eye and Ear Infirmary, etc. New York: G. P. Putnam's Sons. 1879.

This small volume of 300 pages is a key to the technical terms used in German medical literature, many of which are not to be found in the German dictionaries. As such it will prove of the greatest use to translators and readers whose memories are at a loss for the precise synonyms, and we are sure that this result of twenty years' perusal of the German writings, on the part of Dr. Cutter, cannot fail to be appreciated by the profession, especially, perhaps, by those of the younger members who intend to pass a few months or years at the German universities.

Syllabus of a Course of Lectures on Physiology.

By PROFESSOR J. BURDON SANDERSON, M. D., LL. D., F. R. S. Philadelphia: Lindsay and Blakiston. 1880.

This little book of 143 pages contains a very complete and suggestive summary of Professor Sanderson's lectures. It must serve as a valuable note-book to the students who listen to the author's lectures, or are obliged to pass examination upon the same. Naturally the book does not treat of any point at length, and therefore, taken alone, could not be very instructive to a student. On the other hand, if a person were obliged to study physiology without the aid of a teacher, the book would be of great value, because its facts are grouped in such a logical manner that they cannot fail to assist the student in digesting the knowledge which he may obtain from general reading.

Professor Sanderson has also introduced a series of practical experiments upon food and upon the liquids of the body, which any one can try for himself. Finally, the book closes with a number of class demonstrations, which will undoubtedly prove useful to those who have occasion to lecture on the subjects thus illustrated.

The Riviera. Sketches of the Health Resorts on the North Mediterranean Coast of France and Italy, from Hyères to Spezia; with chapters on the General Meteorology of the District, its Medical Aspect and Value, etc.

By EDWARD I. SPARKS, M. A., B. M. Oxon., etc. London: J. and A. Churchill. 1879.

The author of this valuable book has spent many winters on the North Mediterranean coast, and therefore speaks with authority. The work originated in a series of papers, published in the *Medical Times and Gazette* in 1876 and 1877. These have been rewritten and enlarged and many new chapters added. Meteorological tables founded on the most recent and accurate observations attainable have been introduced, and the topographical descriptions, etc., have been corrected up to the present time. The book bears evidence throughout of having been written by one who was anxious to record the truth, rather than by one who was making a special plea for his favorite health resort. We heartily recommend it to all who are seeking information in regard to mild winter climates.

Medical and Surgical Journal.

THURSDAY, MARCH 4, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Osgood and Company, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to Houghton, Osgood and Company, Boston, Mass.

MEDICAL CHARITIES AND THE PROFESSION.

THE injury done to many members of the medical profession by indiscriminate medical charity has been recognized for years, and the medical press has again and again called attention to the flagrant abuses that have grown up in this connection. Of late years, owing to the stress of circumstances, many families, having been forced to reduce their expenses, and the doctor's bill being onerous, and proverbially the last one to be paid, have naturally availed themselves of the generous offers of the various dispensaries, and sought relief where they had free medical advice and "medicine in their own phials." Owing to stress of hard times, physicians, too, like other people, have experienced a great diminution in their incomes, and in seeking to repair this falling off by extra diligence they have found themselves competing with the dispensaries, which offer to attend patients for nothing, and furnish medicine besides. That this is a fair statement of the case can be attested by any physician in active practice near a large dispensary. A young physician recently said that after trying to practice in a certain neighborhood for a year he was obliged to give it up, because everybody, including his landlord and his family, went or sent to the dispensary when they fell sick. Patients attend who are better dressed than the physician whose charity they are abusing; men who own property come and claim a right to free hospital treatment. Many cases in illustration have been communicated by Dr. Sturgis, of New York, in communications to the *Medical Record* and to the Academy of Medicine. A committee of the Philadelphia County Medical Society also has had this subject under consideration (as already reported in the JOURNAL), and has collected a large number of instances of the abuse of medical charities.

Hitherto this evil has been suffered to continue, on account of the feeling that the medical profession had no machinery under their control to enable them to deal with it in a satisfactory way. On the one hand, they saw young men, graduated from college before completing their medical education, eagerly offering their services without remuneration, in order to gain experience or to qualify themselves as instructors; on the other hand, rich but inconsiderate philanthropists, desiring to hasten the millennium by making medical relief free to all who need it, — both praiseworthy objects in themselves, but a combination most unfortunate for less favored physicians who expect to earn their living by practicing in the same community.

The extent of this evil will be appreciated only after a study of the statistics of these rapidly multiplying institutions. It is stated that in London nearly one third of the community obtains free medical relief. The same has been true of Boston. In Philadelphia, with a population of a little over eight hundred thousand, there were treated at the various dispensaries during the year 1879 over one hundred and twenty thousand persons (cases, not visits), after corrections and deductions had been made for overlapping and repeating. From the labors of the Committee of the Philadelphia County Medical Society on Hygiene and Relations of the Profession to the Public, it has been demonstrated that a large number of these applicants could have paid for their advice, as many of them were in the possession of ample means. Forty such cases were reported specifically with their residences and incomes at a recent meeting, when it was decided that some regulation of the dispensary service was imperatively demanded. A public conference between the Philadelphia County Medical Society and the Society for Organizing Charity was therefore held, at which there was a full attendance. Professor Gross was elected chairman, the secretaries being Drs. Charles T. Hunter and F. Woodbury. The chairman made a pointed address, demonstrating the existence of a great evil both to the medical profession and to the public. Dr. H. Lenox Hodge, representing the Society for Organizing Charity, offered its assistance, and made the following recommendations: —

"First, that all applications for relief shall be made in the first instance at the offices of the medical charities. Second, that applicants with families in receipt of nine dollars a week or more, unmarried persons receiving six dollars or more, persons living out at service, are able to employ a physician, and should be refused treatment; and that applicants should be so advised through the cards of the medical charities, as well as by notices placed on the doors of the service rooms. Third, that applicants who may be admitted to treatment shall be required to pay for their medicine, or to deposit ten cents at each visit in a box provided for the purpose, unless exempted through procurement of a certificate of the ward superintendent of the Society for Organizing Charity, on which the words 'unable to pay' shall be noted. This condition should also be placed on the cards and on the notices on the doors of the service rooms."

These recommendations were approved, with the exception of that requiring a specified sum to be paid at each visit.

Dr. F. R. Sturgis, of New York, was present by invitation, and gave a detailed account of the successful working of a similar method of systematic inquiry in the New York dispensary.

Dr. Benjamin Lee presented the following resolutions, embodying the recommendations of the special committee of the County Medical Society, and they were unanimously adopted: —

"Resolved, That efforts should be made to prevent the pauperizing and encraving influences of undue

and indiscriminate medical relief; that care should be taken that the funds contributed by the benevolent to our hospitals and dispensaries be bestowed only upon the poor; that the committee be called 'The Committee on Coöperation of the Medical Charities with the Ward Associations of the Society for Organizing Charity'; that the committee be composed of the medical and surgical staffs of the various hospitals and dispensaries, or representatives from each; that this committee shall call an annual meeting of the profession, at which they shall make a report of what they have accomplished."

We have often called attention to the lax manner in which the medical charities of Boston are administered. Some such attempts as those mentioned above have been made to correct abuses, without great results, however. Reform in this direction would appear to lie within the scope of the new organization of the "Associated Charities," coöperating with the hospitals and dispensaries, to whose further consideration we commend this important subject.

DR. ROBERT WHITE, JR.

ASSISTANT-SURGEON ROBERT WHITE, of the United States Marine Hospital Service, died a few days ago, at his station on Bedloe's Island, at the age of thirty-two. He graduated in medicine at Harvard University in 1867, and after practicing for some years with his father in Boston he went abroad to pursue his studies. He was long at Edinburgh, under Professors Simpson and Lister, and at that time contributed a valuable article to the JOURNAL giving a minute account of Lister's antiseptic method, then in its infancy. Upon his return he entered the United States Marine Hospital Service, where his abilities were soon recognized by his superior officers, and he was detailed by the late Surgeon-General Woodworth to investigate the cause of the yellow-fever epidemic of 1878. He went South, into the heart of the epidemic, in accordance with his instructions, and his researches formed the basis of reports to the Public Health Association, of which Dr. White was a prominent and active member. A letter on Shot-Gun Quarantines, which was published in the JOURNAL while its author was stationed in the South, created much interest, and many readers will miss his occasional contributions to our pages.

He was detailed to go to Alaska on the recent cruise of the revenue cutter Rush, and made a valuable scientific report on his return, which we have already noticed.

Dr. White's fondness for science and energy in the discharge of his duties may have led him to overtax his physical strength, but he accomplished a great deal in a short life, and the branch of the public service to which he was attached has sustained a serious loss.

MEDICAL NOTES.

— Passed Assistant-Surgeon John W. Ross has been promoted eight numbers in his present grade, for extraordinary heroism in risking his life at Holly Springs and Memphis during the yellow-fever epidemic of 1878.

NEW YORK.

— The executive committee which had in charge the contributions in aid of the city hospitals on Hospital Saturday and Sunday, December 28th and 29th, have reported that the total amount collected was \$25,811.60. This includes over \$11,000 of church collections and other offerings sent directly to the treasurers of the different hospitals. Of the balance \$1025 was taken for expenses, \$3454.55 consisted of designated gifts, and was sent to the institutions named by the donors, and \$10,000 of undesignated funds was distributed as follows:—

Mount Sinai Hospital	\$2500.
Presbyterian Hospital	\$500.
German Hospital	\$1000.
New York Eye and Ear Infirmary	\$500.
House of Rest for Consumptives	\$1250.
Home for Incurable	\$1000.
New York Infirmary for Women and Children	\$500.
Orthopedic Hospital	\$750.
St. Mary's Free Hospital for Children	\$250.
The Woman's Hospital	\$500.
New York Ophthalmic Hospital	\$500.
Manhattan Eye and Ear Hospital	\$500.
Hahnemann Hospital	\$250.

In addition to the above results the committee announce that the managers of the Woman's Hospital availed themselves of the opportunity, through various generous contributions, of clearing off a debt of \$20,000 on their buildings. The managers of the New York Hospital coöperated in establishing this general collection, but did not wish to avail themselves this year of any share of the contributions. The managers of St. Luke's Hospital, by whom the collection was suggested, and who for some years have depended on an annual collection from the Episcopal churches for a part of their current expenses, were so generously remembered in designated gifts that they waived all claim upon the undesignated funds. The general committee which had charge of the collections has now been organized on a permanent basis, with the title of "The Hospital Saturday and Sunday Association of New York City."

— The inspection committee of the board of consulting physicians and surgeons to the insane asylums on Blackwell's and Ward's Islands for the months of November, December, January, and February, consisting of M. A. Pallen, W. V. White, and A. McL. Hamilton, have handed in their report, which was unanimously approved by their associates, to the Commissioners of Charities and Correction. At the Ward's Island asylum they state that the condition of affairs is perfectly satisfactory in every way except in regard to the want of accommodation for the large number of patients which the medical superintendent is at present bound to receive. The management was found to be excellent, and upon every side were evidences of good system and the fidelity of the over-

— An assistant medical examiner for Suffolk County is soon to be appointed by Governor Long, the bill providing for such an appointment having been passed by the legislature.

worked medical officers. The patients were well distributed, and as many of the chronic ones as were able were employed in various useful labors. At this institution, as well as that on Blackwell's Island, they continue, are now to be found all the modern improvements in the treatment of nervous and mental disease. The pathological work is done by medical gentlemen who rank high as scientists, and the vast material at their command is utilized to the best purpose.

—Dr. Nagle, deputy registrar of vital statistics, reports that there were one hundred and seventeen suicides in the city during the year 1879. Of these, forty persons shot themselves, sixteen hanged themselves, five jumped from windows, seventeen cut their throats, four drowned themselves, one strangled himself, twelve took Paris green, four opium, one prussic acid, three carbolic acid, one chloroform, four morphia, three arsenic, one illuminating gas, two cyanide of potassium, two oxalic acid, and one rat poison. Fifty of the above individuals were natives of Germany, twenty-nine of the United States, eleven of Ireland, and six of France.

CHICAGO.

—The annual commencements have begun. On the 24th of February that of Rush College occurred. The class graduating numbered one hundred and forty-four. Prof. H. M. Lyman in his address took the ground that, as the work of the student in the medical college was to learn well the elementary facts and principles of medical sciences, and to learn how to study medicine, while the acquisition of the art of being a good physician and of applying these principles to the real problems of life must be chiefly accomplished in the great work of practice and experience outside of the college, therefore three years is as much time as can be profitably spent in college study. The faculty of the college gave a complimentary banquet in the evening to the alumni and special guests to the number of three hundred.

The State Board of Health and the Quacks.—The law under which the board gets a part of its authority—that known as the medical practice act—empowers it to deprive a practitioner of his license to practice for illegal or unprofessional conduct. By virtue of this authority, the board has recently rescinded the license of several of the most notorious quacks in this city. They are men who have been most offensive, not only to the profession, but to all the better part of the general public, in their charlatanism. The board, in this work, is entitled to and has the approval and support of the community. Several other quacks have been called before the board, and are likely to have their licenses revoked. Whether the action of the board will put an end to the practice of these men remains to be seen. The attorney-general has just rendered an opinion that prosecutions for violation of the act—and practicing in the face of a revocation of license is a violation of the act contemplated—are in the nature of criminal proceedings, and must be made and conducted by the State's attorney. This will make the prosecutions very irregular and

unequal in different counties of the State. In counties where the duties of the State's attorney are large, and where the authorities are niggardly in providing him assistants, prosecutions for violation of the medical practice act will be the last prosecutions to be made. It looks very much as though the opinion of the attorney-general, while perhaps very good law, would prove to be in the interest of the quacks. While the board are doing a good work in endeavoring to protect the people from imposition from one class of men, they are licensing, on examination, young junior medical students, who have studied a few months in medical colleges, but who are nowhere eligible to the degree of doctor of medicine, at a rate that causes some men to suspect that they are not doing the public such an astonishing sum total of good, after all.

ST. LOUIS.

—February 10th the St. Louis Academy of Science gave a microscopical soirée, at which a number of very fine instruments were exhibited. In all there were thirty-five microscopes, including five binocular microscopes. Ross, Nacet, Zentmeier, Gundlach, and Hartnack were represented. Among the exhibits were crystallized salicin, shown by polarized light, ferns, crystallized gold, quite a large collection of histological specimens, the circulation in a tadpole, the circulation in a curarized siren, and several living trichinae on a warm stage and in active motion. This was the first attempt at anything of this kind made here, and met with unexpected success. Most of the exhibitors were physicians.

—The College of Physicians and Surgeons gave a banquet on the 11th instant to its board of directors. Dr. Louis Bauer made an address, in which he spoke quite highly of our present health commissioner, Mr. Charles W. Francis. This College of Physicians and Surgeons is not to be confounded with the institution of a similar name founded here in 1869.

—Dr. Charles E. Briggs exhibited to the St. Louis Medical Society quite a rare and a very beautiful specimen in the shape of a menstruating virgin uterus. The patient was a young girl about nineteen years old; for some three months she had not menstruated, but at the time when she should have menstruated had had hæmoptysis. A few days before death her menses reappeared, and the day following, after dancing violently, she was seized with hæmorrhage from the lungs and with dyspnoea. In about twelve hours she died, apparently from gradual filling up of the lungs with blood.

At the post mortem, the uterus was found to be strongly anteflexed; otherwise normal. The left ovary presented a ruptured Graafian vesicle, with a diameter of a little less than half an inch. The mucous membrane of the uterus was hypertrophied and reddened, the hypertrophy stopping very abruptly at about the internal os. The specimen led to quite an animated debate as to whether the uterine mucous membrane is destroyed at each menstruation or not, Dr. Maughs believing that it is, Dr. Engelmann and Dr. Bernays believing that it is not.

Miscellany.

SEA-SIDE ETHICS.

MR. EDITOR.—If practices like the following prevail to any great extent, as we are assured they do, it is quite time, in the absence of a Code rule, to give such "unintentional sinners" a hint that they are at least transgressing the Golden Rule.

Mr. A., merchant, and his family have been patients of a suburban physician more than twenty-five years. Mr. A. was making a visit of a few days at the sea-side when he was seized one night with severe cramp in the right hypochondriac region. He had had such attacks before, which had obliged him to call up his physician in the night to inject morphine subcutaneously, as a last resort. This had usually relieved him, so that he returned to his business the next day or the day after.

On the above mentioned occasion he sent for a Boston physician, who passed his summers near by—for pleasure and profit. The whole history was told; and that Mr. A. intended to return home in a day or two. The physician injected morphine, as had been done on other occasions, and relieved the patient. He called the next day. The second day he volunteered a call, and, saying that he "had been thinking out the case," gave the patient, in writing, his opinions, with recipes and detailed directions for future management. He also requested a letter from Mr. A. in a week after his return home. Mr. A. wrote the letter as requested, in which he stated that he had had another attack before the week was out, and had been obliged to send for his regular attendant.

The directions and the recipes given to the patient before he left the sea-side, together with what was attempted by the casual attendant after the former had reached home and came under the care of his family physician, are as follows, in the language of the doctor himself:—

DIRECTIONS.—"On rising stand in warm water, and sponge body rapidly with water that has been standing in the room twelve hours. Rub dry quickly with thick and soft towels. Wear woolen under-clothing; flannel band round waist; thick shoes; change shoes and stockings on reaching home. Drink one half tumbler of apollinaris twenty minutes before breakfast. Milk and soda water for breakfast, two thirds milk and one third soda water; dry toast, buttered as you eat it, or stale bread and butter; soft boiled egg; a tenderloin steak, or a chop; cold mutton, or poultry; avoid tea and coffee, all hot or fresh bread; lunch at ten o'clock on milk; dine at one o'clock on roast mutton, beef, chickens, lamb,—or chop or steak,—boiled turkey, chicken, partridge, stale bread; one or two glasses of claret; or one of dry sherry, or cider. *Potatoes*, if eaten, to be served mashed and eaten with dish gravy. Vegetables to be used very sparingly. Supper 5.30,—a light meal,—milk and soda water for drink; dry toast and butter or a light farinaceous pudding. *Bedtime*, ten o'clock; cup of beef-tea and toasted cracker, or tumbler of milk; avoid sugar and sweets, pastry, fruit, champagne, and beer, minced and hashed meat, or meat cooked a second time; avoid fatigue, night-air, and dampness. Take quinine one powder in teaspoonful of fresh lemon juice, add table-spoonful of water three times daily. Take bismuth subnitrat, sodæ bicarbonat, acidû hydrocyan. dil., much-

lag. acaciæ, aquæ ad vi. Sig. Table-spoonful ten minutes before breakfast and dinner."

July 4, 1878.

DEAR SIR,—I have read your detailed account with much interest and think we are justified in our treatment. You certainly have done well notwithstanding your severe attack on Monday, July 1st, which was possibly induced by your double dose of Hunyadi Janos, overstimulating the intestines and your easily irritated nerves of digestion. The extremely hot weather has been unfavorable for a healthy and strong digestion. Your attack on Monday came on soon after eating, showing, at any rate, the attempt at digestion preceded and waked up the neuralgia. Your constipation was undoubtedly caused by the quinine, which checks an over secretion from the intestines. I should like to have you give up the present treatment, which appears to be too constipating, and use the following. This ought to relieve the neuralgia, and assist also in digestion: Bismuthi subnitri., lacto-peptine, fl. chart No. 12. Sig. One, in a wafer, ten minutes before breakfast, dinner, and supper.

... Continue the morphine when needed, but not otherwise. Please continue your present regimen and let me hear again from you after one week of present treatment.

Sincerely yours.

July 24, 1878.

MY DEAR MR.—: I am very glad to hear of your continued improvement: certainly your past week has shown a decided gain. In your favor of the 23d you speak of waking with pain Saturday morning [July 20th]. Do you remember anything done or eaten on Friday afternoon or evening that could have induced it? It certainly was a neuralgic attack. Neuralgia is cured by giving the nerves rest. When the nerves of the stomach are implicated we give them rest by food easily digested and taken in small quantities, frequently, and by avoiding exposure and fatigue, causing exhaustion. The prime cause of neuralgia in the digestive tract is a mal-assimilation of food, causing irritation of the mucous membrane and glands of the stomach and intestines. To assist digestion and relieve irritation I prescribe the powders of bismuth and lacto-peptine; to act as a tonic, the tincture of nux vomica and acid. *I want you to continue* them, for I feel that they suit your case and we should err if we stop treatment too soon. I have written at length on this matter, but you will see that the cure of neuralgia depends on the removal of the disturbing cause. I am sure you will be willing to persevere, and shall be glad to hear from you again in a week.

I remain yours truly.

August 7, 1878.

MY DEAR SIR,—I am very glad to hear of your continued well doing; I wish to advise a continuance of the course by which you have been improved. I should like to have you take each medicine *now twice* daily, namely: the powders before breakfast and your mid-day meal. The liquid after breakfast and supper. Of course you will use the same care about diet and fatigue as heretofore. In a week from now I hope we may again decrease the dose and finally omit it entirely. I shall be happy to hear again from you in a week.

Yours very truly.

The foregoing correspondence ended about the time of the letter dated August 7, 1878, the patient adher-

ing all the while to his usual attendant, and always sending for him whenever similarly attacked.

The portion of the correspondence now copied fell into the hands of Mr. A.'s family physician, January 18, 1880. It reveals the most extraordinary conduct on the part of a prominent physician, brought up among, and for many years mingling with, the most eminent and honorable members of the profession. When first called in he knew, he could not avoid knowing, that the patient was about to return at once to his regular attendant. He knew also that the patient did so return, and had an attack a few days after, for which he was treated by this regular attendant. Yet, July 4th, after he knew all this, he writes, directing a change in the treatment he himself had so recently urged, and asks the patient, then at home and under the care of his regular physician, to take this new course of treatment, and to report "after one week." He, this seaside doctor, knew, he could not avoid knowing, that all this was grossest irregularity on his part. He knew, he could not avoid knowing, that if he had anything to say about the case it was his duty, first and last, to correspond with the medical attendant, and not with the patient.

Mr. A. may have thought it discourteous not to gratify a physician who had manifested such zeal in an attempt to promote his future well-being; but Mr. A. had never wavered in his loyalty to his regular attendant, under whose guidance he then was and has continued to be up to the present time; an attendant, by the way, who, through frequent opportunities, might be supposed to know as much as a stranger of the exciting cause of the patient's attacks; and who had never failed in proper diligence or in suggesting preventive measures.

A patient does not always quickly understand why a casual attendant, on so short an acquaintance, becomes so "much interested" (letter of July 4th) in a case. He naturally is not unwilling to listen to specious promises of certain "cure" so disinterestedly held out to him. Sooner or later, however, often too late for redress, an unexpectedly large bill for professional services generally puts a new phase on the affair. The present instance is thought to be no exception to a general rule.

POISONING BY OIL OF TANSY.

MR. EDITOR, — Allow me, through your valuable journal, to call the attention of the profession to some of the poisonous properties of the *Tanacetum vulgare*, or common garden tansy. This perennial herbaceous plant is indigenous in Europe, from whence it was brought to this country, and is now found growing all through the Northern States and Canadas, in gardens and by the roadsides. Both the oil and the plant have considerable reputation in domestic practice as emmenagogues, and also as a means of procuring abortion. The oil has a greenish-yellow color, is lighter than water, and deposits, when undisturbed, camphor. It has the peculiar aromatic and pungent odor of the plant, which once recognized will never be forgotten, and is one of the most dangerous and fatal of our vegetable poisons. The following cases will illustrate my subject: —

CASE I. September 23, 1879, I was hastily summoned to attend an unmarried lady of twenty-nine

years, in previous good health, who, the messenger stated, had suddenly been taken ill, and in a few moments "turned completely black." On my arrival, I found the patient lying upon a sofa, surrounded by her excited friends, who were rubbing her with mustard and other stimulants. Her face, neck, and chest were livid; hands and fingers, especially under the nails, were of a still darker hue. The eyes were partly opened, pupils widely and symmetrically dilated. There was general restlessness, moaning, and after a little time incoherency. Pulse 120 per minute; respiration, 35 per minute and defective. The surface of the body was moist and cool. There was nausea, and I was quite sure I detected the odor of oil of tansy. Her friends, however, were positive in their denial that anything but ordinary food had been taken.

Although she was in a semi-conscious condition, I administered mustard and ipecacuanha abundantly for twenty or thirty minutes, when she vomited copiously, and immediately the house was filled with the odor of tansy. After the emesis the patient became quiet, but the heart's action remained very feeble. I directed general warmth and enemata of whisky in milk, and administered carbonate of ammonia freely. Respiration improved, the heart's action increased in vigor, consciousness gradually returned, and convalescence was established on the following day. I subsequently gathered the following history: At eleven o'clock A. M. she drank about fifteen drops oil of tansy in water. At twelve M. ate a full meal of meat, eggs, bread, etc. At two o'clock she drank about a teaspoonful of oil of tansy in water. Fifteen minutes afterwards she threw herself upon the sofa, saying that she felt "very queer;" then suddenly sprang into the sitting position, uttered a wild cry, and became generally convulsed. Immediately, respiration was apparently suspended, followed instantly by complete and general cyanosis.

The patient would give no explanation of this strange act. The catamenia appeared on the following day, though not due for four or five days.

CASE II. I find the following case reported by Dr. W. W. Ely, of Rochester, N. Y. He was called to a respectable young lady, a school-teacher, who had taken what she supposed was essence of tansy, to promote the catamenial discharge. She took one teaspoonful of the medicine, which proved to be oil of tansy. She first complained of dizziness, and became insensible in about ten minutes. A succession of convulsions ensued, laborious respiration, irregular pulse, and death in one hour and a quarter after taking the poison.

CASE III. The following is an abstract of a case reported by Dr. John C. Dalton, of Boston: A fine, healthy-looking unmarried woman, a seamstress, ate a hearty dinner at five o'clock P. M., seemed happy and cheerful, went to her room at half past nine P. M. About eleven o'clock a scream was heard. On entering her room, she was found on the floor, beside the bed, in violent convulsions. She was totally unconscious; cheeks flushed, and of a bright red color; eyes were open, and very brilliant, pupils widely dilated, symmetrical, and fixed; skin not remarkable for moisture; respiration hurried, labored, stertorous, and obstructed by an abundance of frothy mucus. The breath had a strong odor of tansy. Pulse full, forcible, 128 per minute. At tolerably regular intervals there were

strong spasms, during which the head was thrown back, the arms were raised, and rigidly extended, with contracted fingers. Immediately after a convulsion the countenance was pallid and livid from suspended respiration. As the patient could not be made to swallow, ipecacuanha was thrown up the rectum without effect. She was also bled. Convulsions continued, but were less violent; pulse grew more feeble, and suddenly ceased, immediately after a convulsion. Death in three and a quarter hours after first known symptoms.

Autopsy ten hours after death. Countenance natural, rigor mortis well marked. There was no effusion, congestion, or unnatural appearance anywhere about the encephalon. Heart and appendages normal, and filled with fluid black blood. Interior of heart exhaled a distinct odor of tansy. The same was true of the muscles of the chest. No alteration of pleura; lungs, rather shrunken, crepitated everywhere, were not at all engorged. Nothing remarkable about the air-passages. The peritoneal cavity exhaled a strong odor of tansy, otherwise normal. Stomach contained about twelve ounces of partially digested food mixed with an abundance of small, brownish-yellow, glistening oil globules, exhalant an excessive odor of tansy. The uterus contained a well-formed fetus of about four months, not having been in the least disturbed. Facts led to the conclusion that eleven drachms of oil of tansy had been taken.

CASE IV. I find the following in the *Canada Medical Journal*: A young woman took a teaspoonful of oil of tansy to induce miscarriage. There was coma, dilated pupils, and finally recovery, without action on the uterus.

CASE V. Dr. Pereira quotes a case from the *Medical Magazine*, November 24, 1834, in which frequent and violent clonic spasms were experienced, with much disturbance of respiration. The action of the heart grew weaker, until death took place from its entire suspension. An autopsy showed no signs of inflammation of stomach or bowels. The amount of oil of tansy taken was four drachms.

CASE VI. Dr. Hildreth reports a case of rapid death from a much smaller quantity, with similar symptoms, the poison having been taken to procure abortion.

CASE VII. In the *Medical Times and Gazette*, Dr. Pendleton relates the case of a woman, aged twenty-one, who took a strong decoction of the leaves of tansy to procure abortion. She became incoherent, with contracted pupils; there was afterward coma, followed by paralysis of the voluntary muscles, without spasm or convulsion, and death in twenty-four hours, without action on the uterus.

CASE VIII. Dr. Charles H. Rice, of Fitchburg, has kindly furnished the history of the following case: In January, 1876, he was called to attend a woman three months advanced in pregnancy, who stated that she had taken a strong infusion of tansy daily for one week to produce abortion, without effect. She then used a very strong decoction of the herb (a half pound to a pint, by estimate) as a vaginal injection. In a few hours there was vaginal discharge, first watery, then bloody, accompanied with pain in loins and uterine contraction. Twelve hours subsequently she had a violent chill, at which time the doctor arrived. He immediately administered a hypodermic injection of morphine, and ordered sulphate of quinine, grs. ii., every two hours.

The following morning a digital examination discovered a fetus and membranes escaping from the os. There was also metritis and general inflammation of all the immediate soft parts, with nausea, vomiting, diarrhoea, ischuria, and increased temperature. In a few days a general peritonitis supervened. After a dangerous illness of three months, the patient finally recovered.

From the cases cited above, it appears that neither the herb nor oil of tansy has any specific action upon the uterus, although a strong decoction of the herb, under some circumstances, may act powerfully as a local irritant, as well as a poison, to the nervous centres. It further appears that no antidote of the poison has thus far been discovered, and the proper treatment seems to be to remove the noxious element from the stomach in the safest and most expeditious manner possible. In the case under my care, I should have used a hypodermic injection of apo. morphia, had it been conveniently at hand. Stimulants appear to be essential, in order to continue the action of the heart through the period of depression.

GEORGE JEWETT, M. D.

FITCHBURG, February 12, 1880.

MR. BRYANT AND ANTISEPTIC SURGERY.

MR. EDITOR.—In a recent number of your very excellent journal your London correspondent, in reporting what passed at the debate on antiseptic surgery of December 3d, described my observations as "savage," whereas much of what I said was very complimentary to the distinguished advocate of antiseptic surgery, and I claimed to be an antiseptic surgeon as much as Mr. Lister.

It is true I criticised briefly a paper in which *all* Mr. Lister's joint cases were tabulated, and I expressed surprise that the material upon which the very dogmatic assertions relating to the treatment of joint affections had been based was so limited, but I am not aware that I said one word to justify the use of such a term as your correspondent has used.

The whole debate is, however, about to be published, and you will be able to read for yourself what passed, and to judge fairly. Believe me faithfully yours,

THOMAS BRYANT.

LONDON, February 10, 1880.

THE TREATMENT OF ASTHMA.

MR. EDITOR.—In Dr. F. I. Knight's review of Berkart on Asthma, he incidentally alludes to the results of my treatment of asthma with large doses of iodide of potassium. In connection with the above I desire to state that the drug in doses of five or ten grains seldom gave relief, but large doses continued for a long period gave entire relief in the majority of cases. Some patients, however, were unable to take the iodide of potassium even in small doses; in such cases I used as a substitute hydriodic acid, and, as Dr. Knight says, "with surprisingly satisfactory results." The form I have oftenest used is the syrup of hydriodic acid, and that prepared by Robert Gardner, of New York, I consider the best; it is agreeable to the taste, and not very likely to be affected by exposure to light and air. It should be given as follows: be-

gin with small doses, twenty or thirty drops well diluted with water, and taken about half an hour to an hour before meals; if taken after meals it may disturb the stomach, set up fermentation, and cause colic, acid stomach, and pain in the head; increase the dose gradually, and a tablespoonful dose should not be exceeded. In cases of chronic bronchial catarrh,

and in fact in all cases where iodide is indicated, I have found the syrup of hydriodic acid of great value.

Later in the season I propose to send to the JOURNAL a report of a large number of cases of asthma treated on the above plan, and with very gratifying results.

I am very truly yours,

J. P. OLIVER.

REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 21, 1880.

Two thousand four hundred and forty-eight deaths were reported; 944 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 447, consumption 369, lung diseases 359, diphtheria and croup 155, scarlet fever 76, typhoid fever 44, measles 44, whooping-cough 32, diarrheal diseases 33, erysipelas 23, malarial fevers 27, cerebro-spinal meningitis 19, small-pox eight, typhus fever one. From *measles*, New York 20, Chicago seven, Brooklyn six, Philadelphia five, St. Louis and New Haven two, Buffalo and Charleston one. From *whooping-cough*, Pittsburgh eight, New York seven, Buffalo and Cleveland three, Brooklyn, St. Louis, and New Orleans two, Baltimore, Boston, Cincinnati, Milwaukee, and Chelsea one. From *erysipelas*, New York five, Brooklyn four, Philadelphia and Worcester three, St. Louis two, Chicago, New Orleans, Pittsburgh, Providence, Nashville, and Northampton one. From *malarial fevers*, New York nine, New Orleans six, Brooklyn four, St. Louis three, Baltimore two, Chicago, District of Columbia, and Cleveland one. From *cerebro-spinal meningitis*, Chicago nine, Cincinnati, Holyoke, and Newton two, Philadelphia, Brooklyn, Baltimore, and Fall River one. From *small-pox*, Philadelphia five, Worcester two, District of Columbia one. From *typhus fever*, Baltimore one. One hundred and thirty-nine cases of measles, 45 of diphtheria, 20 of scarlet fever, two of whooping-cough, and two of typhoid fever were reported

in Brooklyn; diphtheria 30, scarlet fever six, in Boston; diphtheria ten, scarlet fever four, in Milwaukee; scarlet fever 43, diphtheria 19, measles two, typhoid fever one, in Providence; scarlet fever 12, diphtheria four, in New Bedford. The death-rate of whites in District of Columbia was 20.98, of colored 41.8. No more cases of small-pox have been reported in Cleveland; it has appeared (during the past week) in two new localities in Worcester.

The total number of deaths reported is about four per cent. less than for the previous week; of deaths under five nearly sixteen per cent. more. There was a very marked diminution from diphtheria, with an increase from cerebro-spinal meningitis and malarial fevers. In 36 cities and towns of Massachusetts, with an estimated population of 1,010,860 (population of the State about 1,650,000), the death-rate was 20.22 against 22.09 and 20.41 of the previous two weeks, with an increase from lung diseases, scarlet fever, erysipelas, and cerebro-spinal meningitis.

For the week ending January 31st, in the 20 chief Swiss towns, lung diseases were very prevalent and fatal, small-pox causing deaths in Geneva and Lucerne. In Belgium, small-pox caused 38 deaths in ten towns; croup was very prevalent, the other zymotic diseases not having been widely prevalent; lung diseases were widespread and very fatal. In Germany there was a diminution in the general death-rate of cities reported 1.5 per 1000. The infectious diseases remained without change or

with less mortality. Lung diseases also were less fatal. Typhus fever and small-pox prevailed in St. Petersburg and Paris. Small-pox had broken out in several parts of Poland. In 143 German cities and towns, with an estimated population of 7,605,712, the death-rate was 25.7 against 27.2 and 26.2 of the previous two weeks. Three thousand seven hundred and sixty-two deaths were reported; 1725 under five; consumption 544; acute diseases of the respiratory organs 462, diarrhœal diseases 169, diphtheria and croup 136, typhoid fever 59, scarlet fever 53, whooping-cough 56, measles and *röteln* 39, puerperal fever 26, small-pox and typhus fever none. The death-rates ranged from 13.5 in Karlsruhe to 41.4 in Altona; Königsberg 34.6; Dantzic 26.6; Breslau 25.4; Munich 24.0; Dresden 21.5; Cassel 16.9; Berlin 24.9; Leipzig 27.6; Hamburg 29.4; Hanover 21.0; Bremen 17.5; Cologne 25.0; Frankfort 17.5. In the same week, Vienna 27.0; Paris 34.1.

For the week ending February 7th, in the 20 cities of England, with an estimated population of 7,499,468, the death-rate was 37.0. Five thousand three hundred and twelve deaths were reported. Lung diseases reached the enormous figure of 1557, largely due to the combined effect of very unusual cold and fog; whooping-cough 317, scarlet fever 120, measles 102, fever 43, diarrhœa 29, diphtheria 13, small-pox (London) 13. The death-rates ranged from 16.5 in Wolverhampton to 48.1 in London; Bristol 29.8; Birmingham 21.2; Liverpool 27.8; Manchester 31.6; Leeds 27.3. In Edinburgh 22, Glasgow 25, Dublin 43 (eight deaths from small-pox). Of the 20 chief towns of Switzerland, diphtheria was fatal in ten, lung diseases being very widely prevalent; small-pox caused deaths in Geneva, Lausanne, and Lucerne.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM FEBRUARY 21, 1880, TO FEBRUARY 27, 1880.

BYRNE, C. C., major and surgeon. Granted leave of absence for twenty days. S. O. 2, Department of Dakota, February 18, 1880.

LORING, L. Y., captain and assistant surgeon. When relieved by Assistant Surgeon D. M. Appel, to proceed to Fort Dodge, Kansas, and report for duty at that post. S. O. 39, Department of the Missouri, February 20, 1880.

APPEL, D. M., first lieutenant and assistant surgeon. Assigned to duty at Fort Supply, Indian Territory, relieving Assistant Surgeon Loring. S. O. 39, C. S., Department of the Missouri.

DRS. GEORGE MCCREERY and EDWARD D. SCHUE, of New York city, RICHARD C. NEWTON, of New York, and JOHN J. COCHRAN, of Massachusetts, having passed a successful examination before the Army Medical Board, now in session in New York city, were, February 10, 1880, confirmed by the senate as assistant surgeons United States Army, with the rank of first lieutenant.

FIBROID PHTHISIS.¹

BY FREDERICK C. SHATTUCK, M. D.

The term phthisis, like the term Bright's disease, represents a group of pathological conditions, not, like the term typhoid fever, a single and invariable pathological condition differing in different cases only in degree and more or less accidental complications. This group consists, according to modern pathology, of three members, tubercle, pneumonic infiltration or exudation, and interstitial growth, the fibroid substitution of Bastian. It is true that in the majority of cases of phthisis we find two or all three of the members of the group coexistent and intimately associated with each other; but we do, on the other hand, meet with cases in which some one of the members is alone, or almost alone, represented, as in acute miliary tuberculosis, acute inflammatory phthisis, and cirrhosis of the lung or fibroid phthisis. It is with the latter that we are concerned to-day.

I would define it as a chronic disease of the lungs, the vesicular structure of which in the affected part or parts is destroyed and replaced by connective tissue growth, generally unilateral and associated with bronchial dilatation, running its course without notable fever or emaciation, but, in the long run, directly or indirectly fatal.

When the greater part or the whole of one lung is involved, great distortion of the thorax and dislocation of the heart and neighboring organs may result from the diminution in volume of the diseased, and compensatory hypertrophy of the sound lung. The affection may be confined to one lobe, as in a case I saw some years since. The patient was a laboring man, who had been apparently healthy, but succumbed on the third day to an acute pneumonia of the right lung. At the autopsy the lower lobe of the left lung was found to be converted into a dense mass of fibrous tissue traversed by dilated bronchial tubes. Pleuritic adhesions are nearly always present, sometimes lax and slight, sometimes very thick and tough, even fibro-cartilaginous in appearance. In only one of thirty cases tabulated by Bastian was any fluid found in the pleural cavity. The tissue of the lung is very firm and resistant, and may even creak under the knife, and varies greatly in appearance, chiefly according to the degree of bronchial dilatation and the amount and character of the pigmentation, which latter is derived either from the blood or from the inhalation of particles of foreign substances, such as coal or iron dust and the like. The bronchial dilations, not invariably present, may equal or even surpass a hen's egg in size, and are uniform, fusiform, saccular, or globular in shape. The contents may be purulent, muco-purulent, somewhat inspissated, or thin and excessively offensive, entirely independent of gangrene. Any patches of relatively normal lung which may remain near the indurated tissue are apt to be markedly emphysematous, as is often also, to a less degree, the sound lung. This is, partly at all events, the result of the frequent and long-standing cough. The most important and frequent change about the heart is hypertrophy and dilatation of the right cavities from mechanical obstruction to the pulmonary circulation. In the last stages of the disease this is

liable to be followed by general dropsy. Bands of white glistening fibrous tissue are sometimes seen passing through the lung, but a mottled gray and black coloration is more common, leading Addison to compare the appearance to that of Aberdeen granite, and Rindfleisch to employ the term "slaty" or "schistous" induration. Miners' lung may be uniformly black, as well as the fluid which is squeezed out from the cut surface.

I will not detain you long with a discussion of the pathology of the affection, in regard to which there has been so much controversy, and is to-day such wide difference of opinion. A striking illustration of this diversity is afforded in Reynolds's System of Medicine. Dr. Wilson Fox contributes an article on chronic pneumonia, and, with an interval of a few pages, Dr. Bastian succeeds him, and treats of precisely the same condition, equally at length, under the heading of Cirrhosis of the Lung, the term given by Sir Dominic Corrigan more than forty years ago. Fox denies, Bastian affirms, its existence as an independent disease. The former says that "nearly all the cases of pulmonary induration which have fallen under my observation have been connected with previous chronic pneumonia associated with the presence of tubercles;" the latter that, though chronic lobular pneumonia, tubercle, and the miliary process are frequently combined, there is no necessary connection between them, and each may and does exist by itself as an independent affection. According to Jaccoud the process is primary only in hard drinkers. The mode of production of bronchiectasis has also been a much-disputed point since it was first described. As connected with fibroid phthisis the two chief factors in the production are probably increased pressure within the tubes during attacks of cough, and diminution in the size of the lung beyond the limit provided for by contraction of the chest wall and displacement of organs. The etiology is pretty clear except as to the question whether the condition is ever primary, and there is no doubt that it is very often secondary to bronchitis, pleurisy, croupous and catarrhal pneumonia.

The symptoms vary greatly in character and prominence with the area of pulmonary tissue involved, the absence or presence of bronchiectasis, and the stage of development reached by the affection. When it is limited to one lobe, symptoms may be nearly or quite wanting, but when it is extensive, cough, expectoration, and dyspnea, especially on exertion, are usually well marked. The expectoration may be very profuse, notably after rising in the morning, and has often a faint, sickish, disagreeable smell. Fetid expectoration indicates either gangrene or retention and decomposition of the secretion. If there be marked bronchiectasis we may have the expectoration characteristic of that condition, namely, the discharge at intervals of large quantities of secretion, the patient during the interval being nearly free from cough and expectoration. Hemoptysis is common, and apt to be frequently repeated and moderate in amount, unless it proceed from an eroded vessel in a cavity. Fox mentions a case in which it recurred seventy times in twenty-three years. Fever and emaciation are mostly confined to two classes of cases, — those in which the disease is the direct sequence of a croupous pneumonia which never underwent resolution, and the course of which is relatively short, and those in which tubercle and lobular pneumonia appear and reappear on the scene and

¹ Read before the Essex North District Medical Society at their semi-annual meeting, January 13, 1890.

bring the drama to a close. General dropsy from failure of the right heart has been already alluded to, and albuminuria is not uncommon. Laryngeal symptoms are absent, the appetite is usually good, and diarrhoea, when it occurs, is rather a complication than a true feature of the disease.

The diagnosis is often easy, though it may be attended with great difficulty. Our main reliance must be on the lack of correspondence between the rational signs and history and the physical signs. The latter are those of pulmonary consolidation and excavation, while the general condition of the patient often shows that we are not dealing with the ordinary form of phthisis. I saw at Schrötter's clinic at Vienna a remarkably plump and blooming young girl with flatness on percussion, bronchial voice and breath sounds and gurgling râles all over the base of one lung, and was assured by Schrötter that to his knowledge the girl had been in this condition for a number of years.

In unilateral cases with contraction it is not always easy to exclude chronic pleurisy, though the authorities state that it can usually be done. According to Walshe, curvature of the spine and drop of the shoulder on the affected side do not reach so high a degree in cirrhosis as in chronic pleurisy. Dilated bronchi may be met with in both affections, though they are perhaps more constant in cirrhosis. But the most conclusive evidence is a history of repeated hæmoptysis which points strongly to cirrhosis. A history of tapping excludes, of course, primary cirrhosis, and some value must, it seems to me, be attached to the fact that a patient has never been tapped. The confidence with which we now plunge a fine aspirator needle into almost any part of the body undoubtedly diminishes largely the number of undetected or doubtful pleuritic effusions. The history of the case alone will ordinarily suffice to enable us to exclude malignant disease. In the last stages of the disease, when secondary inflammatory or tubercular changes are present, difficulties in diagnosis may arise, but careful analysis of the history and the sequence of the symptoms will generally enable us to arrive at the true nature of the case.

The prognosis cannot be regarded as favorable, though it is of course much more favorable, as far as duration of life is concerned, than in cases of destruction of an equal amount of lung tissue by the common phthisical process. There are no means within our reach for restoring the vesicular structure, and the tendency of the disease is to progress more or less slowly and invade new territory, even if no more rapid process supervenes, or an intercurrent affection, as is often the case, carries off the patient. Fætor of the expectation, whatever its cause, is an unfavorable symptom, as are also, of course, fever, emaciation, albuminuria, and dropsy.

It follows from the foregoing that treatment must be chiefly hygienic and symptomatic. The patient is to be guarded as far as may be from fresh colds, and a cold, when acquired, is not to be made light of. Fresh air and sunlight, woolen clothing, a generous diet, and the avoidance of severe exertion, which throws extra work on the already overtaxed heart, are of the greatest importance. Sedative cough mixtures may be required to procure sufficient sleep, and fetid expectation may be combated by inhalations of carbolic acid and the like.

These are briefly the salient features of fibroid phthisis, and I will now venture to present a patient who

illustrates very well the part which connective-tissue growth plays in the cure—temporary though it may be—of ordinary phthisis. You have doubtless all of you seen similar cases, but they are not very common, and this particular case is so strongly marked that I think it will not be without interest.

J. A., forty years of age, was sent to me early in September, 1879, by my friend Dr. Bradford. His grandfather died of asthma, and two brothers out of nine have died of quick consumption. He served four years in the navy during the war, contracting typhoid and intermittent fevers. After his discharge, in 1865, was strong and hearty, and worked in a printing-office. In October, 1870, caught cold while house-moving, from exposure, and from this cold he dates his present troubles. Though he had persistent cough did not consult a physician for upwards of a year, at the end of which time he had night-sweats, and was so much run down that he sought advice. Was told by the physician that he had chronic bronchitis. Kept steadily at work, consulting his doctor now and then for the next two years, and was then told that he was in danger of consumption. Spat blood for the first time in 1872, since when has had attacks of hæmoptysis, recurring at intervals every spring except that of 1879. Is positive that he must have spat blood at least eighteen or twenty times, the last time in October, 1879. Between 1875 and 1877 worked off and on. Was laid up once for ten months, once for five, and alternately lost and gained in weight. Since the spring of 1877 has been able to do no work. His weight was at that time at its lowest point,—one hundred and eighteen pounds,—and he began to drink Medford rum, a quart of which a week was given him by a friend. Since then has gradually gained in flesh, and now weighs one hundred and seventy-one pounds, the greatest weight which he ever attained before his sickness began being one hundred and sixty-seven pounds. Between September 4 and December 2, 1879, gained ten pounds. Has had the opinion of many physicians during these years, and has been twice an inmate of the Boston City Hospital. All agreed in the opinion that he was in consumption. Gives a history at one time during his sickness of expectation as from a large cavity. On leaning forward at times large quantities of secretion poured out of his mouth, leaving him comparatively free from cough and expectation, until the cavity again filled and was emptied.

He now complains of dyspœa, greatly aggravated by exertion, and cough with profuse mucopurulent expectoration, especially on rising in the morning. Is greatly troubled by the fact that his acquaintances refuse to believe him a disabled man, and intimate that he is shamming. Sleeps in an easy-chair by preference, though he can lie down if his head and shoulders are well raised. Is not affected by changes of weather or draughts.

There is decided flattening and deficient expansion of both upper fronts, and the integument over the supra-clavicular space is drawn inwards during inspiration. There is also marked dullness on percussion on the upper part of both lungs front and back, especially the right front and left back, with intensification of the voice sounds and very harsh but not bronchial respiration. Over the base of both lungs percussion is not remarkable, and respiration is more or less obscured by abundant coarse, moist, and dry râles.

There is hypertrophy of the right ventricle, as is

shown by accentuation of the pulmonic second sound. There is no marked cyanosis of the lips or face, but the terminal phalanges of the fingers are clubbed to an unusual, those of the toes to a less, degree; slight oedema of the ankles. Urine has a specific gravity of 1017; shows a trace of albumen, and under the microscope hyaline and finely granular and fatty casts.

To recapitulate: A vigorous man of thirty contracts bronchitis from exposure, neglects it at first, and after a period of between two and three years inflammatory phthisis develops and cavities form in his lungs. In the course of time the catarrhal process ceases to advance; active connective-tissue growth gets the upper hand, obliterates the cavities in great measure, and so contracts the volume of the lung that the chest walls fall in over the upper fronts. With the cessation of the inflammatory process the bodily weight comes up, but so large an area of vesicular and capillary structure has been destroyed that the breathing power can respond to only the most moderate calls upon it, circulation is seriously impeded, and secondary changes supervene in the kidneys from passive congestion. The cavities not being completely obliterated, secretion persists, is retained, and tends to permanent bronchitis and the establishment of new foci of lobular pneumonia and interstitial growth.

NOTE. During the second week in February, 1880, the subject of the above history became insane, and, threatening the lives of his family, was sent to the Danvers Asylum February 14th. February 20th he was found dead in his bed, and I was so fortunate as to secure his internal organs, through the courtesy of the medical officers of the institution. The organs were submitted to Dr. E. G. Cutler, who kindly makes the following report, which it will be observed, bears out the diagnosis fully. The dyspnoea was not greatly aggravated during the last weeks of life:—

AUTOPSY

about thirty hours after death. Both lungs were very firmly adherent at the apices, slightly so over portions of the bases. The upper lobes of both lungs were greatly shrunken, especially in the upper halves, and very dense to the touch. On section, the vesicular structure of these portions was seen to be replaced by connective-tissue growth with marked peribronchitis and a number of bronchial dilations, the largest of which was about the size of a hickory-nut. These changes were most marked near the anterior aspect of the right and the posterior aspect of the left apex. There was considerable emphysema of the lower portions of the upper lobes of both lungs, and general chronic bronchitis, but no foci of lobular pneumonia or cheesy nodules. The left lung was also more or less oedematous in portions, and the main branch of the left pulmonary artery contained an extensive embolus, partially broken down and slightly adherent to the wall of the vessel. The right ventricle was markedly dilated and hypertrophied, the tricuspid valve admitting four fingers with ease, and the right auricular appendage contained an old thrombus similar in character to the plug found in the pulmonary artery. The left heart was in every way normal. The kidneys were somewhat cloudy, but there was nothing especially remarkable about any of the other organs or the brain.

— The distinguished Lockart Clarke is dead.

RECENT PROGRESS IN INSANE ASYLUM MANAGEMENT.

BY WALTER CHANNING, M. D.

A GLANCE AT INSANITY AND THE MANAGEMENT OF THE INSANE IN THE UNITED STATES.¹

DR. EARLE, in this paper, read at the Conference of Charities in September, 1879, goes again into the question of the curability of insanity. Pursuing the same line of argument as in previous papers, he first shows the fallacy of statistics collected in insane hospitals during the last fifty years. From 1837 to 1847, some of the most prominent men in the specialty, such as Woodward, Bell, Aul, Brigham, Kirkbride, Stribling, Ray, and McFarland, were in charge of insane hospitals. To the enthusiasm of these men we owe the many excellent results obtained in the treatment of insanity. "Such a body of men, acting at a time in which the enterprise for the insane was in its most plastic and impressionable stage, could not fail to leave upon it the lasting evidences of their ability." The zeal and rivalry among the various superintendents gave rise to false statistics. Dr. Todd, in 1827, got a percentage of recoveries of over ninety-two, but these were founded on the recovery of twenty-one out of twenty-three cases; and Dr. Woodward, in 1836, using the fallacious method of calculating recoveries on discharges, of 84½. During the past forty years the percentage has fallen, and in no series of one thousand cases has even a percentage of sixty-six been obtained.

The time is coming when an immense number of chronic insane must be provided for, and we must have asylums peculiarly adapted for them. The greatest objections to these institutions, namely, *danger of imperfect oversight and inspection*, has been done away with. The Willard Asylum is recommended as a model for such institutions.

REPORTS OF MASSACHUSETTS STATE INSANE HOSPITALS FOR 1879.

Dr. Earle continues his researches into the statistics of insanity in his report of the Northampton Hospital for the year 1879, under the heading of Studies Relative to the Curability of Insanity. In this he refers to a table copied from the report of the Worcester Lunatic Hospital for 1843, and republished in connection with a memorial by Miss Dix, for the purpose of showing the remarkable advantage, pecuniarily, of the treatment of insanity in its early stages. This table presents two columns, or series of cases, twenty-five in each. Those of the first column were chronic and incurable; those in the second were recent, and had been discharged from the hospital in the course of the year, recovered. It occurred to Dr. Earle that it would be interesting to follow the subsequent history of the twenty-five recent cases which recovered. In summing up the results which he obtained, he finds that only seven of them did not have a second attack, and eighteen had more than one attack. As so many are still living it is impossible to state the result in regard to the number dying insane, but already seven have died insane. In this connection Dr. Earle gives the well-known formula of Dr. Thurman, "that of ten persons attacked by insanity five recover and five die, sooner or later, during the attack. Of the five who recover not more than two remain well during the rest

¹ By Fliny Earle, M. D.

of their lives; the other three sustain subsequent attacks, during which at least two of them die."¹

In the report of the Worcester Hospital it is stated that a series of tables has been compiled from the records of the hospital containing the results in all cases since the opening of the hospital, about 11,000 in all. The superintendent states that the most important inference to be drawn from these tables is that the record of recoveries for any one year is very largely fallacious, in so far as it conveys the idea of a permanent return of patients to their homes. The old tables, giving seventy, eighty, and ninety per cent. of recoveries, are almost entirely unreliable.

The trustees of the Danvers Hospital have appointed a female assistant physician, and express satisfaction with the appointment. (There are, I believe, at present three assistant female physicians in asylums.) During the year a pathologist was appointed to the hospital. He has made six autopsies. In only two cases were there any lesions of the brain. These consisted of necrosis of brain tissue in one case, and inflammation of the membranes and the surface of the brain and atrophy of the convolutions in the other. Whether microscopic examinations were made is not stated.

FIRST ANNUAL REPORT OF THE STATE BOARD OF HEALTH, LUNACY, AND CHARITY IN MASSACHUSETTS. 1878.

The first report of this board is necessarily brief, covering but a few months, but it presents some statistics in that portion devoted to lunacy which are of interest here. The total number of insane people in Massachusetts at the present time cannot be much under five thousand. October 1, 1878, there were 2830 insane persons in the various insane hospitals and asylums in the State. During the year 1297 admissions (representing 1000 persons) to these establishments took place. There were 282 patients discharged recovered, and 253 died; at the end of the year 3017 remained. Taking these numbers together with the number of insane persons in almshouses and prisons, and it will be seen that there were 3335 October 1, 1878, and 3562 October 1, 1879, in all public and private institutions. The actual increase in the number of insane persons supported at public expense would appear to be 227 for the year. This makes an addition of twenty persons to the insane population monthly. Increased accommodations must be provided for at least two hundred persons yearly. The conclusion is arrived at (based on figures) "that the great majority of those discharged from our hospitals, otherwise than by death, go forth insane." Of 5200 actual discharges for five years, not more than 1150 can have been permanent recoveries. Among the 559 patients at Taunton, the superintendent estimated only 83, or about one in seven, as possibly curable. At the Worcester Hospital, with 860 patients in both departments, less than forty were regarded as curable, or about one in twenty-one. At the Danvers Hospital, with 533 patients, but few more than fifty, or one in ten, could be classed as probably curable. Some uniform basis for insane hospital statistics may soon be adopted, and

insanity in Massachusetts will then be better understood. Investigations are going forward which, when completed, will help to settle the vexed question of: (1) whether insanity is more frequent than formerly; (2) whether insanity is curable to the same extent as other diseases; (3) whether insanity can become well enough understood by the medical profession and public as to be practically preventable in any number of cases.

THE SEPARATE CARE AND SPECIAL MEDICAL TREATMENT OF ACUTE AND CURABLE CASES OF INSANITY IN ASYLUMS.²

Dr. Burman begins his paper by referring to the fact that public attention is chiefly occupied with efforts to provide better and more cheaply for the incurable, or vast majority, while the interests of the curable, or minority, are almost lost sight of. The care of the curable cases is more especially the work of the asylum physician. Dr. Burman quotes Dr. Thurman M. Leiznt, Baron Mundy, Dr. Lockhart Robertson, Griesinger, and Lord Shaftesbury as in favor of separation. He states that the number of curable cases remaining at the end of each year at the Wilts Asylum, while he was superintendent, was only seven per cent., which was a most liberal estimate. This very smallness of number he regards as an argument in favor of separation. While the chronic or incurable can be cared for in the main building, the curable cases should have a separate, detached hospital. The duration of the curable stage is very short, three quarters of the recoveries at the Wilts Asylum from 1869 to 1879 having taken place in nine months. Such being the case every nerve should be strained and every known appliance used to take advantage of this short period. "The question is whether this can be satisfactorily done while the curable cases are mixed up with others and scattered all over the large main building, or whether we might not more advantageously move them together in a small, detached hospital, to be the objects of special care and solicitude, observation and treatment. In such small hospitals the general superintendence of hospital details would be subordinated to the medical treatment of the patients." "It is too often the case at present that medical officers have to hurry away from important medical duties to complete their general task of daily routine." Dr. Clonston, in another place, is quoted as saying, "It is the patient's turn for an innings now. We have heard of nothing in asylums for twenty years but bricks and mortar, ornamentation and recreation; it is surely time to fall back upon our almost forgotten employment of doctors."

In the special small hospitals, among other external remedies the following should be used: (1.) Baths of all kinds, and the water treatment generally, including Turkish and Roman baths, medicated baths, the cold douche, wet packing, the ice bag, etc. (2.) Electricity. (3.) Light and darkness, and the colored light, as recommended by Ponza. (4.) Gymnastic exercises. (5.) Counter-irritation in its various forms. Internally, such remedies as nitrous oxide gas and nitrite of amyl should be employed, and subcutaneous injection should be more practiced. "Conia needs only a fair trial in subcutaneous injection to be of great and decided benefit in acute mania." Hyoscyamine is worthy a wider

¹ Backnill and Tuke state, in the last edition of their work, that "it would be strictly correct to say of eleven persons attacked by insanity six recover and five die, sooner or later, during the attack. Of the six who recover, not more than two remain well during the rest of their lives; the other four sustain subsequent attacks during which at least three of them die."

² By J. Wilkie Burman, M. D., Journal of Mental Science, October, 1879, and January, 1880.

trial. Considering the functional nature of disorders comprised within the term insanity, and that in most cases functional disorder must at any rate precede organic lesion, it is to be regretted that more use is not made of atropia, ergot, calabar bean, etc., and less of morphia, bromide, and chloral. With these remedies we could better strike at the root of disease. Compressed and rarefied air might be of value in certain cases. The latter, as stated by Parkes, causes "quickened pulse and respiration, increased evaporation from the skin and lungs, and on the whole a marked improvement in digestion and in nervous and muscular vigor." Either might be applied, as in the establishments at Lyons and Reichenhall, by placing the patients for a certain time each day in an iron chamber with thick plate-glass windows, and compressing or exhausting the air.

THIRTY-THIRD ANNUAL REPORT OF THE COMMISSIONERS IN LUNACY IN ENGLAND, 1879.¹

The number of registered insane persons in England January 1, 1879, was 69,885. The proportion of insane persons to the population was, in 1859, 1 in every 553; in 1869, 1 in every 418; and in 1879, 1 in every 360. This increase is largely confined to pauper patients, but the opportunities for the concealment of cases is so much better in the upper classes that the relative number registered is much smaller. While insanity, congenital and acquired, is somewhat more frequent among males than females, the rate of recovery is higher among females than males, but the mortality is so much greater among the latter than the former that the females largely preponderate over the males in the total number under care. The commissioners speak strongly in favor of the continuance of private asylums and licensed houses.

TWENTY-FIRST ANNUAL REPORT OF THE SCOTCH COMMISSIONERS IN LUNACY, 1879.¹

The number of registered lunatics in Scotland January 1, 1879, was 9386, showing a net increase of sixty-one per cent. since 1858. The increase of population during this time has been only nineteen per cent. Investigations have been made to determine the topographical distribution of insanity, which show that it exists to a much larger extent among the urban than among the rural population. The commissioners refer to the unlocked doors and the absence of fences at some Scotch asylums. It would seem that an unusual amount of supervision would be necessary, together with a larger number of attendants and accidents; but the cost is only five and one half pence larger a head per week, and the number of accidents is no greater than in English asylums.

INSANE HOSPITALS OF EUROPE.

In the Proceedings of the Sixth Annual Conference of Charities, Rev. F. H. Wines gives an interesting and intelligent account of a visit he made to sixteen English and Continental asylums. The classification of patients in foreign asylums because of social distinctions is entirely different from that with us; private and pauper patients cannot be mixed together. The influence of climate upon architecture and manners is very marked. In the south of England the thermometer ranges from 28° to 85° F., while in Illinois

its range is doubtless: It is therefore evident that arrangements for heating which answer admirably in England or France, and out-of-door life, must be more restricted. This difference in climate is also an answer to what Dr. Bucknill supposed to be the overheated condition of our hospital wards. English superintendents occupy the same position toward the camisolé that American superintendents occupy toward the shower-bath. They admit its value in certain cases, but banish it on account of its liability to abuse. Physical exercise largely takes the place of restraint. "What would you do," Mr. Wines asked of an English superintendent, "with that man in a paroxysm of excitement?" "Do?" he replied. "Put him in charge of two attendants, with instructions to walk him five or six miles and back; and if, on his return, he should prove to be still in an agitated state detail two other attendants in their place to repeat the dose." The shower-bath is extensively used in French institutions. A complete bathing establishment is almost indispensable in a well-managed asylum. The visitor "is shown a long row of copper bathing-tubs of the usual pattern, except that they have copper covers, which are locked, with an opening just large enough to show the head." Sometimes a patient is kept soaking in there five or six hours. A physician watches the patients to see that the pulse does not sink too low. There are *donche* baths; needle-baths, so that the patient can be drenched with spray or showered; hip-baths, and iron cages where the patients can be penned in and fired at from the nozzle of a hose-pipe in the hands of an attendant. No practicable form of torture has been omitted.

The lower floors of French asylums are occupied by day, the upper by night. On the ground floor are the dining-room, with little tables arranged as in a Parisian café or restaurant, smoking and billiard rooms, and sometimes a music-room. In good weather, patients dine out-of-doors, and the gardens, to which patients repair at will, are made attractive with little summer-houses, lighted at night with gas. Dormitories are the rule in both English and French asylums, which is the reverse of our American custom. Many of the upper windows have no guards in the French asylums, and open fires are quite general and unprotected in English asylums.

The "open-door" system Mr. Wines saw in operation in Scotland, at Cupar-Fife and Lenzie. At Cupar he walked through the front gate of the asylum directly into the wards. At Lenzie there are five hundred patients, but not one locked ward. The officers carry no keys; there are no window guards, yet there are no more accidents than under a stricter rule.

At Cheadle (England) an interesting experiment is in progress. The asylum farm contains one hundred and forty acres, and the number of patients is two hundred. Sixty of these patients live in cottages. Three of the cottages are in the grounds; the rest are private residences, scattered through the neighborhood, some at a distance of several miles; one is at the seaside, for recreation. The superintendent or assistant physicians visit the cottages daily, on horseback or by carriage.

ISOLATION OF PERSONS IN HOSPITALS FOR THE INSANE.

Dr. Isaac Ray read a paper on this subject before the Philadelphia Social Science Association, last October. The idea now prevails that legislatures should

¹ Jour. Ment. Science.

² Jour. Ment. Science.

prescribe the forms of commitment which should be gone through in sending persons to insane asylums, but the question is so biased by the influence of passion, prejudice, and temperament that it can be settled only with great difficulty. Persons are confined to their homes, deprived of their liberty, and even subjected to personal restraint, if suffering from insanity, outside of a hospital. Why should they not be sent to institutions for treatment, without interference from society? The law of Pennsylvania declares that insane persons may be placed in insane hospitals by their legal guardians, provided such a proceeding is sanctioned by the certificates of two physicians. It is said that physicians may be dishonest or deceived, and it is not right to give them the sole power of committing to the hospital, and so disposing of a person's liberty; but in "signing a certificate of insanity a physician performs a professional service, in which he is amenable to his own sense of right and wrong and responsible to the laws of his country. Under what stronger obligations and sanctions can one act?" The medical certificate is all-important, but the physicians are so poorly protected that some of them in Philadelphia, to avoid a law-suit, will sign no certificates. At a time when a whole family is bowed down with grief, and the patient himself in a highly irritable condition, all unnecessary complications should be avoided, for they will only make the grief of the family greater, and develop suspicions, and perhaps delusions, in the mind of the patient. On the whole, therefore, medical certificates are, in Dr. Ray's opinion, the only safeguards needed in committing persons to insane hospitals.

Hospital Practice and Clinical Memoranda.

A REMARKABLE CASE OF CARCINOMA.

BY C. H. BROCKWAY, M. D., LYNN, MASS.

ON the 8th of December last I was called to see Mrs. A. G., a lady not quite thirty years of age. She was sitting up, and complained of pain "all over," as she expressed it. She would not admit that it was more severe in one region than another, only that it did not exist above the shoulders or below the hips. After some cross-examination I concluded that she really suffered most in the hypogastrium, across the abdomen, in the right hypochondrium, and at a point just below the inferior angle of the right scapula. I could find no tenderness on pressure except over the right ovary. By passing a finger into the vagina, the uterus was found to be immovable and slightly retroverted; anterior and a little to the right of it was felt a small, easily defined mass of moderate firmness, evidently the result of cellulitis. I pressed upon the tumor and in other directions, but she said it gave her no pain. She was exceedingly nervous, and slept but little. She could lie only on her right side, saying that it took away her breath when she lay on her left. There was no cause for this peculiarity that I could discover. Her pain came on suddenly three weeks previously, and had steadily increased in severity; she was tolerably free from it in the forenoon, but every afternoon about four o'clock it became so severe that she had been obliged for some days past to take morphia for its relief. She described it as gnawing, grinding pain, never sharp and lancinating. Her pulse was

88, and of fair strength; temperature five r. m. 99.5° F.; heart sounds normal; appetite poor, but she took animal broths, bread, fruit, and milk with lime-water without distress; bowels constipated; liver somewhat enlarged from above downward; no symptoms referable to the kidneys or bladder. Inquiring into her past history, I learned that she had considered herself in fair health since her childhood, only that at intervals of a month or more during the past three or four years she had suffered from gastralgia. Last October I saw her in one of these attacks; there was neither vomiting nor purging, only pain in the region of the stomach and liver, with anorexia. This lasted two or three days. I made but one visit, and gave her an anodyne, which relieved her. Two and a half years ago she married, and has since had two miscarriages, each between the third and fourth months; the second one occurred last July. She suffered little at either time; did not remain in bed except on the first day, but went about her household duties, which were quite onerous, she being step-mother to three children. Her menstruation has been regular and nearly painless, with but moderate flow. I learned that her mother died of some obscure disease of the liver.

Mrs. G. said that six years ago she was quite plump in appearance, but during the past two years had grown very thin. Her complexion was bad, but not cachectic. I ordered her bowels to be opened by enemata every other day, gave her small doses of iron and strychnia, and allowed her morphia at night.

December 11th. No improvement; ordered a blister, three by three, over the right ovary, and allowed her to be rubbed with an anodyne liniment.

December 18th. Pain continuous throughout the day; she is much depressed, and says she does not expect to recover. She prefers sitting to lying down, and cannot walk about the house without feeling exhausted. She now complains of severe pain over the liver below the ribs, and points out a small spot which is quite tender on pressure; a blister is applied, and quinine added to her other tonics.

December 22d. Weaker; complains of inability to fix her attention, and says she is "dazed" at times; no headache; on pressure over the tender spot in the right hypochondrium a small, poorly defined mass is felt, somewhat hard to the touch; pulse 93; temperature five r. m. 101° F. As her insomnia was distressing, I gave her fifteen grains of chloral at night; it made her wild with excitement, and was not repeated. She took morphia both day and night, but never more than one grain in the twenty-four hours.

December 25th. As no diagnosis had been made, and she was fast losing her strength, I asked Dr. Pinkham in consultation. We met at four p. m. Mrs. G. was sitting up, as usual, and in reply to questions concerning herself she referred us to her sister, saying that her head felt strange, and that she could not readily collect her thoughts. Pulse 100; temperature 102° F. Dr. Pinkham examined her per vaginam, and found a condition existing such as I have previously described, with the addition of tenderness on pressure in various directions. The hardness over the right lobe of the liver was made out, but Dr. Pinkham thought it might be caused by irregular contraction of muscular fibres. Her breath was very disagreeable, and had been for weeks. Her only symptoms at this time were exceedingly weakness and an inability to lie on either side, continuous pain, chiefly over the liver and under the

right scapula, insomnia, and complete anorexia. She could walk about the room, but required help because her head felt dizzy. Dr. Pinkham advised the use of iodides, with tonics and good nourishment; also flying blisters over tender spots.

Ten hours later, at three A. M., December 26th, I was sent for, and arriving quickly at her bedside found her totally unconscious, with complete hemiplegia of the left side; pupils evenly contracted; breathing natural; pulse 120, and hard. On examination per vaginam the roof of the pelvis felt boggy on pressure, as if fluid of some kind had been effused into the pelvis. Externally, a very hard, irregular tumor, the size of a small hen's egg, could be felt in the left ovarian region, and was easily movable. Alcohol and drop doses of Squibb's fluid extract of digitalis were given every half hour until six o'clock, when Dr. Pinkham again met me. No change was made in the treatment except that the digitalis was omitted, as her pulse had fallen to 100, and was weaker.

During the day small quantities of alcohol and beef tea were given at short intervals. She would swallow slowly if carefully fed with a teaspoon. The patient would toss the right arm about, and flex and extend the right thigh and leg incessantly. She lay in this condition for five days, the faces and urine passing involuntarily. On the sixth day she began to breathe stertorously, her pulse grew weak, and she quietly expired at one A. M., December 31st, never having regained consciousness.

Sectio cadaveris thirty-six hours after death. Drs. Pinkham and Colman present. The body was emaciated. *Thorax.* The lungs exhibited a number of isolated masses when viewed externally, each mass about the size of a small pea; they were raised above the surface, and felt firm and hard; large numbers of them were found on the posterior aspect of each lung, and still more were seen just under the parietal pleura. *Abdomen.* The lower part of the cavity contained about a pint of a sanguinolent fluid; peritonæum covering abdominal wall was studded with nodular masses like those in the lungs. The omentum was very thick and irregular in shape from the presence of hard, conglomerate masses of grayish color; it was firmly bound to the surrounding intestines, which were also studded with grayish masses. The liver was enlarged, and nodules were found in numbers on its surface; on cutting into the organ its proper substance was to a great extent infiltrated with a similar matter. The pancreas was partially diseased in like manner. The spleen was considerably enlarged. The proper substance of both ovaries was destroyed, and its place occupied by firm, grayish matter. The ovaries had a shriveled appearance, their surface being covered with alternate elevations and depressions. The uterus was not examined.

For want of time the skull was not opened, but we had every reason to believe that the matter found so extensively infiltrated through the other viscera was present in the brain, and had been the cause of an effusion of serum or of blood which had produced the hemiplegia and was the immediate cause of death.

Microscopic Examination. Dr. Pinkham kindly examined portions of the grayish material found in the ovaries and liver. Under a power of three hundred diameters there was clearly seen a fibrous stroma with alveolar spaces, closely packed with masses of cells of

various forms, round, oval, and spindle-shaped, with large, single, and some with multiple nuclei.

We looked upon this case as remarkable because of the almost total absence of symptoms during life, while the autopsy revealed such extensive infiltration of cancerous matter through many organs. Until the middle of November Mrs. G. felt fairly well, and performed much household work, besides sewing for her family. From that time until a week before her death her only symptoms were wandering pains, increasing in severity at night, and tenderness over small spots in various regions, not unlike what is often observed in neuralgia. Physical examination during the last week of life revealed the evidence of subacute cellulitis which three weeks before I had looked upon as chronic. She had neither cough, nausea, vomiting, diarrhoea, external hemorrhage, tympanites, oedema, nor even fever, until within the last few days. She had not the cachectic look so often seen in cancerous patients, nor was any real tumor discoverable until she was stricken with death, when an effusion into the pelvic cavity buoyed up the hardened left ovary so that it could be felt through the abdominal wall.

Scirrhus cancer is acknowledged by all observers to be very rare before middle life, yet the patient whose case I have recorded had not quite reached the age of thirty.

A CASE OF TYPHOID FEVER DURING PREGNANCY.

BY VIRGIL O. HARDON, M. D.

K. F., aged thirty-four, became pregnant for the fourth time in January, 1878. Her pregnancy progressed favorably until about the first of August, when she began to suffer from malaise, loss of appetite, headache, and chills. Her symptoms increased in severity until August 9th, when she sought medical aid. When first seen by me she was in bed; her face was flushed; her tongue dry and covered with a thick brown coat; abdomen tender, with gurgling in the right iliac region; pulse, 120; temperature, 102.4° F. Examination of the abdomen showed the presence of "rose spots." I made a diagnosis of typhoid fever, prescribed a mixture of equal parts of liq. ammon. acetat. and aq. camphor, and ordered milk and brandy to be given as freely as possible. August 10th. Six P. M. Pulse, 126; temperature, 103.2° F. August 11th. Six P. M. Pulse, 136; temperature, 103.8° F. August 12th. Eight A. M. Pulse, 122; temperature, 102.8° F. Active delirium during the night. Ordered quin. sulph. gr. iv. every three hours. Six P. M. Pulse, 144; temperature, 104.4° F. Upon inquiry I found that my orders in regard to milk and brandy had been strictly carried out. The patient had taken, of her own accord, six quarts of the former and about eight fluid ounces of the latter in each twenty-four hours. As there was no vomiting, no diarrhoea, and no appearance of undigested milk in the feces, the same quantities were allowed to be continued. Up to this time there were no symptoms referable to the uterus.

August 13th. At two A. M. labor pains commenced, and three hours later patient was delivered of a male foetus, which made a few ineffectual attempts at respiration. No hemorrhage of any consequence followed, and the womb contracted immediately. The strength of the patient was not perceptibly diminished. At eight A. M.

the temperature had fallen to 98° F., and in the evening rose to 100.2° F. No delirium.

From this time onward the fever pursued a course of moderate severity, the temperature at no time rising above 101° F. The same large quantities of milk, brandy, and quinine were taken until two weeks later, when convalescence was established. The patient made a good recovery.

Typhoid fever during pregnancy is rare. In regard to the influence of this complication upon the course of the disease authorities differ. Out of fourteen hundred and twenty cases of typhoid fever seen by Liebermeister¹ in the hospital at Basle, only eighteen occurred in pregnant women. Of these eighteen, fifteen aborted and six died. Griesinger² met with five cases, of which three proved fatal. Niemeyer³ says, "Pregnancy gives almost absolute immunity from the disease." Playfair⁴ reports twenty-two cases, of which sixteen aborted. He does not give the mortality. Schroeder⁵ says that the immunity is not so great as was formerly supposed, and that on the whole the disease does not take a more unfavorable course in pregnant woman than in other individuals. Cazeaux⁶ gives the result of his experience in the following words: "La fièvre typhoïde a rarement été observée pendant la grossesse, et ne paraît pas recevoir de cette coïncidence une influence fâcheuse." I have myself seen a case, in addition to the one above reported, in which the fever occurred in the third month of a first pregnancy. Abortion followed, and the woman died.

A remarkable fall of temperature immediately following abortion was observed by Liebermeister⁷ in all his cases, and was attributed by him to loss of blood. He found that the temperature always rose again within twenty-four hours to a point as high as before the abortion. In the case reported above, the temperature fell to about the normal point immediately after abortion occurred, but did not rise at any time afterwards to within three degrees of the point at which it stood on the evening previous. I attribute this circumstance to the fact that large doses of quinine were given on the day before the abortion, and continued throughout the remainder of the fever. The value of quinine as an antipyretic is now well established. I cannot, however, agree with Liebermeister as to the best method of administering the drug. He says,⁸ "This dose [twenty-two to forty-five grains] must positively be taken within the space of half an hour, or, at the most, an hour. It is useless to expect the full benefit of this dose to appear, if the dose is divided and its administration extended over a longer time." I have obtained more satisfactory results by giving four grains every three hours throughout the day and night than by giving a single large dose once a day. I have never been able to detect any signs of cinchonism during typhoid fever, although I have frequently given thirty-two grains per day for more than two weeks. In view of the oxytocic effect ascribed to quinine, it is interesting in this case to note the promptness with which abortion followed the administration of this remedy. The

fact that the fœtus was born alive has an important bearing upon this point, since, according to Schroeder,⁹ abortion during typhoid fever is due to the death of the fœtus, within the uterus, from excessive accumulation of heat.

Another point of interest in connection with this case is the amount of milk and brandy taken by the patient throughout the whole of her sickness, which was certainly large enough to satisfy the most ardent advocate of "supporting treatment." The milk taken was wholly digested, no part of it being vomited or appearing in the feces. The brandy produced no intoxication, although the patient was unaccustomed to the use of alcoholic stimulants. In my opinion, this portion of the treatment contributed in no small degree to the successful issue of the case.

PROVIDENCE, February 11, 1880.

A PIECE OF METAL TWENTY-THREE YEARS IN THE EYE WITHOUT CAUSING SYMPATHETIC OPHTHALMIA.

BY JULIAN J. CHISOLM, M. D., BALTIMORE, MD.

I. N. M., aged thirty-nine, applied to the Presbyterial Eye and Ear Charity Hospital of Baltimore for treatment. He had lost the right eye from injury twenty-three years before. A gun-cap, exploding, struck him in the eye, cutting the cornea, and causing irido-cyclitis, through which inflammation the eyesight was lost. He was then a lad sixteen years of age. When the destructive inflammation quieted down the conjunctiva lost its redness, the cornea keeping its transparency, and the eye retaining somewhat its normal appearance. He has been a hard-working man all his life, and yet this injured eye has been in a passive state, giving him no trouble. Only recently has it taken on inflammation and shown degenerative changes. When he presented himself for treatment the eyeball was partially atrophic, somewhat corrugated, the cornea smaller than normal, but clear, and surrounded by a zone of ciliary injection, with some large subconjunctival vessels advancing from the back of the eye to the corneal border. The pupil was altogether closed by old deposit, and upon the iritic surface near the centre was a yellowish-white spot of about two lines in diameter. This reflected light, and induced the belief that it might be a fragment of the copper cap. The eye was painful, very sensitive to the touch, and exhibited all the symptoms for an early enucleation. The left and good eye gave evidences of irritation. Extirpation was performed under chloroform, the anæsthetic in daily use at the hospital.

When the eyeball was cut open the retina was found completely detached as a cord stretching antero-posteriorly through the centre of the eye chamber from the optic-nerve entrance to the ciliary region. A muddy fluid filled the choroidal cavity in which was a diaphanous choroidal membrane nearly deprived of pigmentation. The lens was cretaceous. In examining the iris, especially with reference to the glistening spot upon its anterior face, a fragment of the cap was found imbedded in lymph, and therefore shut out from view. It was the inflammatory deposit which had incarcerated it that had given the yellowish-white reflex which had attracted attention through the cornea. The interest

attached to the case was that a piece of metal cutting into the eye with force enough to excite destructive traumatic inflammation could afterwards remain in the lost eye for twenty-three years, during this long period causing no trouble, and then exciting anew a powerful inflammation which threatened sympathetic irritation to the good eye.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

F. C. SHATTUCK, M. D., SECRETARY.

OCTOBER 6, 1879. DR. BOARDMAN read a paper entitled

SOME OBSERVATIONS ON THE TREATMENT OF UTERINE DISPLACEMENTS.

The paper was reserved for separate publication. He advocated strongly a tolerably extended use of pessaries of a dumb-bell shape composed entirely of cotton-wool, and reported some cases to illustrate the successful application of his method.—DR. BAKER thanked Dr. Boardman for his interesting and valuable paper. One of the cases in particular illustrated very well the great importance of preparing the vagina to receive a pessary. It is far too common to attempt to use a hard instrument from the first; indeed, as Dr. Boardman shows, the cotton pessary will often enable us to dispense entirely with a hard form. The form shown corresponds in some respects with one described some years since in the *New York Medical Journal*, but differs in two important points; that of Dr. Boardman contains no whalebone, and is applied transversely, while the New York form is applied in the axis of the uterus. Even if it proves necessary finally to use a hard pessary, the cotton dumb-bell will often so prepare the way that a decidedly smaller hard instrument will attain the ends which could at first have been attained only by a larger one.

INNOMINATE ANEURISM.

DR. BEACH reported a case of innominate aneurism which had gradually developed in a man of thirty-seven years without known cause. When he entered the hospital the prominent symptoms were aphonia and more or less pain in the vicinity of a pulsating tumor, which had a well-marked thrill, and extended for an inch and a half above the sterno-clavicular articulation. There was a considerable difference in the pulsation of the two radial and temporal arteries, those of the right side having less force and volume. Tufnell's method of treatment was adopted with good effect up to the twenty-eighth day, the pulsation in the radial and carotid arteries of the affected side having in the mean time stopped; the tumor had become firmer, and the thrill was less perceptible. From the twenty-eighth day his respiration became more and more labored; as the tumor grew harder and its expansive pulsation diminished, his dyspnoea grew worse. On the forty-eighth day after the treatment had begun, he coughed, and felt something "give way" in the tumor. From that time he grew worse rapidly, bronchitis developed, dyspnoea increased, and he had occasional attacks of asphyxia, from which he was with difficulty relieved, dying quietly three days after. Upon exami-

ination after death the aneurism was found to involve the innominate artery and sufficient of the arch of the aorta to include the organs of the left subclavian and carotid arteries, the tumor extending from a point one inch and a half above the top of the sternum to the arch of the aorta (four and a half inches); the innominate portion of the aneurism was partly filled with laminated fibrin. This clot had been forced upward against the origins of the subclavian and carotid arteries by the arterial current, and had partially stopped them, thus accounting for the absence of pulsation in those vessels and their branches. The arch of the aorta was dilated to three times its normal size, and there was a hypertrophied left ventricle of the heart. Old clots were found adherent to the mitral and tricuspid valves. The lungs were oedematous; the trachea was flattened at the seat of the tumor, and filled with a frothy, muco-purulent fluid. The right lung was adherent to the chest wall. The pericardium contained half an ounce of turbid serum. The right recurrent laryngeal nerve had been compressed by the tumor.

A NEW ANTISEPTIC.

DR. BEACH showed a specimen of styrene (styryl alcohol or cinnyl alcohol, C_9H_9O or C_9H_7OH). It is obtained by heating styracin or cinnyl cumamate (a compound contained in liquid storax and in balsam of Peru) with caustic alkalies. It crystallizes in soft, silky needles, having a sweet taste and an odor of hyacinths, melting at $33^\circ F.$, and volatilizing without decomposition at a higher temperature. It is moderately soluble in water (about one part to twelve), freely in alcohol and ether.¹ Dr. Beach had tested the efficiency of the antiseptic by applying it (one part to twelve of water) to a foul, ulcerated surface, with the effect of completely deodorizing it. The same surface was dressed with sheet lint saturated with an emulsion of the styrene and olive oil, one part of the former to twelve of the latter, covered with thin gutta percha and the edges of the gutta percha fastened to the skin by collodion. At the end of five days the dressing was removed, and the accumulated secretions were found sweet, and having the odor of the styrene, which is fragrant. This dressing was repeated at different intervals with a like result; the granulating process progressed as well as if it were under a carbolized or thymolized dressing. The pure styrene is slightly irritating to a raw surface, causing a burning sensation, but diluted to one part in six either of oil or water the result is a non-irritating emulsion. In either form it is a perfect deodorizer of a foul wound, and does not interfere with the process of cicatrization. One part in twelve of oil or water is sufficiently strong to be effective. To determine the relative efficiency of carbolic acid, thymol, and styrene, the following test was made: Three ounces of normal urine from the same specimen were placed in each one of four clean glasses. To the first glass was added ten drops of pure carbolic acid, to the second ten drops of pure thymol, to the third ten drops of styrene, and to the fourth nothing. The open mouths of the glasses were filled with borated cotton to protect the urine from dust. On the second day the urine without an antiseptic became decomposed, and was thrown away. The first specimen, containing carbolic acid, was offensive from the smell of decomposing urine on the sixth day, and under the microscope presented bacteria in the monad and rod

¹ Fowne's Chemistry, Philadelphia, 1869, page 554.

forms; it had a strong urinous odor from the first day. The second and third specimens, preserved by stryrene and thymol, were in good condition at the time of making the report, fifty-nine days later, and were free from any urinous or offensive odor. No fungoid forms could be detected under the microscope at that time.

DR. BEACH reported the following cases of

RECOVERY FROM SEVERE INJURIES

at the Massachusetts General Hospital.

CASE I. A man twenty-six years old fell forty feet with several tons of stone and a derrick. Upon examination it was found that he had the following injuries: a compound comminuted fracture of the ulna at the junction of the middle and upper thirds, and an extensive lacerated wound of the soft parts, laying open the elbow-joint; a compound fracture of the tibia in close proximity to the knee-joint, and two scalp wounds. The elbow-joint was completely excised, and the loose upper fragment of the ulna removed. A suppurative synovitis of the knee-joint followed, with severe constitutional symptoms, for which the joint was laid freely open, drainage tubes were inserted, and the whole joint carbolized. The leg was placed upon an excision splint, and attention paid to thorough drainage, carbolizing the wound, and stimulating the patient. His temperature ranged from 90° to 105.5° F., and his pulse from 95 to 145. He left the hospital with a stiff knee-joint, but a serviceable leg. His arm was useful, the false joint permitting free extension, supination, pronation, and rotation, notwithstanding the loss of the insertion of his brachialis anticus. He was able at the time of making the report to work all day in a blacksmith's shop wielding a sledge hammer, and had almost perfect use of his hand and fingers.

CASE II. The second case was that of a man thirty-four years old, who had, one half hour before entering the hospital, sustained the following railroad injury: compound, comminuted fractures of the bones, and laceration of the soft parts of both legs, ankle-joints, and feet. The right thigh was amputated at the junction of the middle and lower thirds by the oval method, and the left limb just below the knee-joint by anterior and posterior flaps. Obstinate vomiting began soon after the operation, and lasted for the greater part of five days. His strength was supported in that time by stimulating and nutritive injections, and very small quantities of champagne and Valentine's beef extract by the stomach. He was discharged, well, six weeks from the day he entered the hospital.

OVARIOTOMY: DEATH FROM INTERNAL HÆMORRHAGE.

DR. A. T. CAROT showed an ovarian cyst removed the week before by Dr. J. H. Homan. The case was favorable for operation, the cyst being unilocular and free from adhesions, and illustrates the danger of catgut ligatures. The patient did well till night, when the nurse noticed that she was weaker, and called the house officer, but the patient died before he could reach her. The abdominal cavity contained a large quantity of blood, and one of the ligatures seemed to be loosened, but no particular vessel could be selected as the source of the bleeding. The operation did not last above forty minutes.

DR. HOSMER reported a case of Supposed Phlebitis of the Lung.¹

¹ Vide JOURNAL, vol. ci., p. 726.

OCTOBER 20, 1879. DR. BOLLES read a paper on

CASES OF COLLES'S FRACTURE,

showing a new splint which he has devised and uses with the best results. He claimed for his method increased comfort for the patient and diminution in the length of time that the splint must be worn, as well as in the degree and persistence of stiffness in the fingers and wrist after the splint is removed. The paper was reserved for future publication. — DR. PORTER inquired whether Dr. Bolles knew the subsequent history of many of his cases. He noticed that in some the splint had been removed on the eighteenth day. The class of people who fill our out-patient rooms are apt to think that they are entirely well as soon as a splint is removed, and begin immediately to use the hand as if nothing had happened. The consequence is that the deformity is apt to return. — DR. BOLLES replied that the splint had been removed as early as the eighteenth day only in cases of separation of the epiphysis. Adults always wear the splint four to five weeks. — DR. PORTER then remarked that he considered even four weeks too short a time. He had seen cases in which the splint was removed thus early, and in which deformity persisted. If the form devised and shown by Dr. Bolles favors more rapid and permanent repair, it will prove a great convenience to surgeons, but it is well to exercise great caution, in view of a suit for malpractice. — DR. BOLLES said that he hoped he had not conveyed the impression that he is in the habit of removing the splint by the calendar, — he always waits for firm union. He had seen many of his cases subsequently, — one after an interval of six months, — and there was no return of the deformity. — DR. PORTER spoke of a case which had convinced him that there is movement in the callus. A boy of twelve years was referred to him by Dr. Ellis, with marked deformity after a Colles's fracture of six weeks' standing. Very strong pressure was applied and the arm put in proper position, with the result that after six more weeks it could not be distinguished from its fellow. — DR. BOLLES did not think that the union could have been bony, or it would not have given way. — DR. INGALLS expressed his satisfaction with the paper, and asked the reader whether he had met with marked and persistent inability to move the fingers and impairment of motion at the wrist. — DR. BOLLES said that he could not recall any case of the kind after a considerable time had elapsed. He remembered one case in which motion was not very good after six weeks. — DR. INGALLS said that this question was prompted by the recollection of a case in which Dr. Bolles's splint was applied by his assistant, and which has since proved very troublesome. The splint was left in place for eight or nine weeks, and although no deformity remained, stiffness of the fingers is still very marked. The patient is of lax fibre, and may perhaps have done no better after any injury or appliance. — DR. T. B. CURTIS alluded to the so-called displacement or subluxation of the lower end of the ulna, so often reported in cases of Colles's fracture, and occasionally even said to exist without any displacement of the radial fragment. He asked the reader if he did not think that any apparent displacement of the lower end of the ulna should always be considered significant in reality of a displacement of the lower end of the radius, carrying with it the carpus and hand. The ulna being the only bone which remains in its place, the alterations of its rela-

tions must be due solely to a displacement of the other bones. He also inquired of the reader to what extent and for how long he is in the habit of confining the fingers. He had often observed that the stiffness of the hand and fingers following an otherwise successful treatment gave more trouble than the fracture itself. — DR. BOLLES replied that the fingers were immobilized in but very few of his cases. He considers it better to leave the fingers free, provided that the carpus is confined, and to this freedom of the fingers he attributes the early use of them noted in his cases. He agreed with Dr. Curtis in the opinion that patients often suffer more from the consequent stiffness than from the fracture, and thinks that a fortnight is saved by leaving them free. With Dr. Curtis's remarks as to subluxation of the ulna he also agreed entirely. — With regard to the relationship supposed to exist between the degree of displacement and the amount and duration of subsequent disability, DR. CURTIS stated that fractures into the wrist-joint are probably not infrequent and must entail more serious consequences than attend ordinary fractures, even with considerable tilting of the fragments. He then alluded to Dr. Bigelow's case of stellate comminuted fracture of the lower end of the radius.¹ The *Bulletins of the Anatomical Society of Paris* recently contained the report of the post-mortem examination of a case of double Colles's fracture, in which both of the radial fragments were split into several pieces. In one wrist the tip of the styloid process was torn off; in both the triangular ligament was more or less detached from the ulna.² With such injuries a considerable degree of arthritis would be likely to occur. — DR. BOLLES called attention to the fact that in his list of cases those past middle life did as well as younger people. As a rule the degree of deformity and subsequent stiffness in his experience correspond pretty closely. — DR. J. C. WARREN remarked that great stress should be laid on the importance of thoroughly reducing the deformity, to do which more force is required than is generally supposed. The small size of one of the fragments and the fact that the fracture is apt to be impacted add to the difficulty. It is the lateral deformity which is liable to persist, the antero-posterior being corrected by the splints. With regard to the case mentioned by Dr. Ingalls, Dr. Warren thinks that surgeons meet with such disagreeable cases from time to time. The confinement of the fingers certainly contributes to subsequent stiffness, but he noticed formerly, when surgeon to outpatients at the Massachusetts Hospital, that protracted convalescence usually goes with feeble intellect. Intelligent people know, or find out soon, how to use the hand, and how not to do so. He remembered a case in which the stiffness lasted for nearly a year. — DR. DWIGHT stated that he has had large experience with the reader's splint, and has found it excellent. — DR. LANGMAD asked on what principle the splint was devised. — DR. BOLLES replied that when a dresser at the City Hospital he had noticed the difficulty in so padding a splint that it would fit and allow itself to be applied to the whole arm, and soon after Dr. Fifield brought back from Europe a splint with a wooden pad devised by Mr. Gordon, from which he took his idea.

CARIES WITH PERFORATION OF THE PATELLA.

DR. BRADFORD showed a patella removed from a

child brought to the Children's Hospital with what was supposed to be knee-joint disease. After consultation with Drs. Ingalls and Langmaid, aspiration was practiced but without much result. Subsequently the dermis which was seated over the patella was probed and found to lead directly through the patella into the joint — purulent synovitis. The joint was laid open, and the child died of shock twelve hours later. On examination, after death, caries of the centre of the patella was found, and the synovial membrane of the joint was thickened and covered with granulations. The femur, tibia, fibula, and cartilages of the joint were healthy.

CEPHALHEMATOMA.

DR. SABINE showed the specimen removed from a child seven weeks of age. About a week before death the child refused food, had slight diarrhoea, and vomited somewhat. At the autopsy no sufficient cause for death was found, and no symptoms pointing to the head had made their appearance during life. — DR. C. P. PUTNAM remarked that the specimen was very interesting. Cephalhematoma is always recovered from, and anatomical specimens are consequently rare.

NOVEMBER 3, 1879. DR. BRADFORD read a paper on Cases of Tracheotomy, an abstract of which, with the discussion which ensued, will appear in the first number of the *Journal of Laryngology*, shortly to be published.

PROCEEDINGS OF THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

MALARIAL PUERPERAL FEVER.

At the last meeting of the New York County Medical Society, January 26th, DR. FORDYCE BARKER read an important paper on the above subject, which was listened to by a large audience. This title, he said, in commencing, was one that had not as yet been adopted by the scientific world in the nomenclature of diseases, but at the present day it was almost impossible for those who were at all largely engaged in obstetric practice to get along without resorting to some such term. For several years now he had himself been in the habit of employing it, and he believed that it was beginning to come into pretty general use among the profession in the city of New York. Moreover, the affection thus designated was of such importance that it was worthy of very careful study on the part of all who are interested in the practice of midwifery, and he felt assured that he could not occupy the time of the society in a more profitable manner than by inviting their attention to some consideration of the subject.

The occurrence of chills, high temperature, rapid pulse, and great depression of the vital forces in a puerperal patient, he continued, must always cause anxiety in the medical attendant, and especially if these symptoms, real or simulated, were accompanied by phlegmasia of the pelvic organs, or followed by mania or other serious phenomena; and it at once became a very important matter to decide whether the attack were due to septicaemia or to the telluric and miasmatic influences which we describe as malarial. He did not mention puerperal peritonitis as among the affections simulated by, and likely to be confounded with, malarial puerperal fever, for the reason that it had never happened to him to meet with the

¹ JOURNAL, vol. lviii. p. 99.

² Bull. de la Soc. anat., May, 1877, page 382.

characteristic symptoms of either the sthenic or septicæmic form of peritonitis in a case of the latter affection. He had notes of seventeen cases of the disease in New York and its suburbs; only three of which, however, had occurred in his own practice, — the other fourteen having been met with in consultation with other practitioners. The limits of the present paper did not permit him to give the full details of these cases, which were in his possession; and he proposed only to make some statement of their aggregate results, and the conclusions at which he had arrived from their study.

As to the time of infection, the disorder could be developed at any period following parturition until all the physiological changes resulting from the latter had been completed. The earliest case that had come under his observation was one that he had seen in consultation with Dr. Howard Pinckney, and in this instance the attack commenced only twenty-four hours after delivery. After doing perfectly well up to this period, the patient was seized with a violent chill and acute pain in the left groin, extending down the thigh. Then followed high fever and profuse perspiration. Dr. Pinckney, thinking the trouble probably due to malaria, ordered quinine in large doses; but, unfortunately, the drug was not well borne. He therefore called in consultation a very eminent obstetrician of this city, and the latter pronounced the case one of well-marked septicæmia. The temperature was 105° F. at the time that he saw the patient, and he therefore advised that she should be kept on a water-bed, and that cold affusions should be made to the abdomen; which was accordingly done. Soon afterward, however, the temperature fell to its normal degree, and the next time that the consulting physician saw her, he frankly acknowledged that he was mistaken. The quinine was then renewed in smaller quantities; but as it did not have the desired effect of controlling the fever, which again returned, Dr. Barker was called in. He recognized the case as undoubtedly one of malarial puerperal fever, and suggested that quinine should be given in very full doses, but in connection with bromide of potassium, on account of the tendency to cerebral congestion which had been found to result from it previously. This was tolerated perfectly, and the patient then became rapidly convalescent.

The case in which the affection was longest in making its appearance occurred in Dr. Barker's own practice. It was on the twenty-first day after delivery that the patient was seized with a severe chill. This was soon followed by high fever (the temperature running up to 105½°, and the pulse to 128), and she became decidedly delirious. There was no abdominal tenderness whatever, and a vaginal examination proved negative in its results. Twenty grains of quinine, with one grain of codeia, were ordered to be taken at once, and the same to be repeated in the evening. She then passed an excellent night, and the following day felt perfectly comfortable, although rather weak. The above remedies were now continued in half the previous doses; but afterwards she had another similar attack, even more severe than the first, and the large doses were again ordered to be repeated, with the addition of five grains of calomel. On the same day that the fever and delirium returned she had a profuse uterine hemorrhage, and on each of the three following days she took no less than sixty

grains of quinine and three grains of codeia, in addition to a considerable quantity of tincture of the chloride of iron, tincture of nux vomica, and fluid extract of ergot. Afterwards she made a good recovery.

The most prominent symptoms of malarial puerperal fever, Dr. Barker went on to say, were chills followed by a higher temperature than is ordinarily met with in other puerperal diseases so soon after their onset. After such an explosion there occurred a remarkable remission on the following day, and the physician was very apt to imagine that the trouble was now all over, and that the treatment which he had adopted had been most successful. The delusion was removed, however, when on the first, second, or third day afterward the attack was renewed with equal or even greater severity. Dr. Barker was inclined to believe that in the greater proportion of cases the patient began to suffer from general *malaise* three or four days before the occurrence of the explosion, and that when this was the case the latter was apt to be less severe than when the attack burst out in full force without any premonition. This form of the disease, he thought, was also more protracted in its duration and less amenable to treatment than the other. In some cases it was very liable to be mistaken at first for ordinary puerperal fever, as the symptoms were often strikingly like those of the latter, and the discrimination had to be made with great care. In others the attack closely resembled phlebitis, and this had been the case in one of his own patients.

In one of the three cases occurring in his own practice (where the malarial affection had made its appearance on the sixth day after confinement), the cure was finally accomplished by means of the hypodermic injection of quinine in large doses. This, unfortunately, produced abscesses; but in no other way was it possible to introduce a sufficient quantity of the drug into the system. It was important to bear in mind the fact that malarial puerperal fever might occur in connection with any of the phlegmasiæ incident to the puerperal state. In several of the cases, beside the one mentioned, uterine hemorrhages had been noted as a result of the malarial poisoning. In some of these it was observed that the lochia became very offensive in odor towards the end of the hemorrhage, and Dr. Barker thought the explanation of this was that, the blood being poured out very slowly at this time, it underwent decomposition in the cavity of the uterus before a sufficient quantity had accumulated to force its way out at the os by exciting contractions in the organ. In one of the hemorrhagic cases purpura was noticed as a result, and in this instance convalescence was very slow; recovery not being complete, indeed, until the patient had spent several months in Europe. In no case, so far as was known, had there been any blood in the urine.

Dr. Barker next spoke of delirium or mania as a symptom of this malarial disease. It occurred in four out of the seventeen cases. In three of them there was delirium rather than mania, while in the fourth there seemed to be mania, as the mental excitement continued for several days. In one case, which he saw in consultation with a physician of Jamaica, Long Island, he found the patient almost in a semi-comatose condition, and at first felt confident that she was suffering from uræmia. The examination of the urine, however, showed no evidence whatever of any such trouble; but still, notwithstanding this, he could not

divest his mind of the idea that there must be uræmic poisoning present, and so advised the use of Clutterbuck's elaterium. This produced free purgation; but instead of being benefited by the treatment, the patient only grew worse. He now became convinced that the symptoms were due to malaria; but the attending physician was very reluctant to accept that view of the case, and to prescribe quinine in the very large doses that he suggested. As the latter had come to regard the case as hopeless by this time, however, he at last consented; and after some morphia and atropia had been preparatorily employed the patient was given one drachm of Lente's solution of quinia. This was repeated every three hours; so that in twenty-four hours she received eighty grains of quinine. The next day the patient was perfectly rational, and the physician now became as enthusiastic over the treatment as he had previously been skeptical.

After this the convalescence was rapid. It was worthy of note in connection with this case that the patient never once complained of pain in the head, ringing in the ears, or any other symptom of cinchonism; and it was found, as a general rule, that there was in all the cases a most remarkable tolerance of quinine.

One fatal case occurred out of the seventeen. The patient, who was seen in consultation with Dr. Hall, had been married only a year, and had spent the three years previous to her marriage in Rome, Italy. Her mother was of the opinion that she had contracted malaria even before she went abroad. The confinement was a normal one in every respect, and she did perfectly well up to the thirteenth day afterward; when she had a violent chill, which was followed by fever, though there was nothing abnormal about the puerperal functions. She was given thirty grains of quinine, and the next day, the fever continuing, she took thirty grains more. It was not until the third day that the remission occurred, and the case was then regarded as one of remittent malarial fever by the attending physician, and by Drs. Thomas, Metcalf, and Barker, all of whom saw her in consultation at different times during her illness. For many days she took on an average sixty grains of quinine a day. Later there was profuse leucorrhœa, and also slight cystitis; and at one time there was a secondary uterine hæmorrhage, which was followed by fetid-smelling lochia.

In the latter part of her illness Warburg's tincture was substituted for quinine. At first it was followed by so much improvement that there seemed a likelihood of her recovery; but it appeared to lose its effect, and she grew worse again. A fatal termination was reached on the forty-seventh day after confinement; and this was, no doubt, one of those cases in which the system had become so saturated with the malarial poison that no remedial agent yet known to science could have saved the patient's life. In a number of instances Warburg's tincture had been found much more efficient than quinine, and Dr. Barker said that he usually gave half an ounce of it every four hours until the symptoms disappeared, when the dose was gradually diminished; though the remedy was not entirely relinquished until complete convalescence was established, and if there was any return of the malarial manifestations, however slight, the large doses were at once resumed.

DISCUSSION.

The subject of the paper now being thrown open for discussion, Dr. HALL, in whose practice the fatal case just alluded to had occurred, remarked that the toleration of quinine in this instance was most extraordinary, since in the height of the fever the patient frequently took one hundred and fifty grains in the twenty-four hours, and yet never once complained of any *cinittus aurium* or other symptom of cinchonism. He also spoke of the use of the nitrite of amyl, which he had employed with good effect during the excessive prostration which accompanied the period of chill in this case. He could not say that it had cut short the length of the chill; but it certainly did seem to fortify the powers of the patient in such a way that she was the better able to endure the high fever that followed.

Dr. HANKS, who had been the attending physician in one of the cases mentioned by Dr. Barker in which hæmorrhage was a prominent feature, stated that in his patient there was more loss of blood when the child was born than he cared to see, and that she had flowed excessively after the delivery of the placenta; so that he was now convinced that she was even then suffering from the effects of malarial poisoning. The pulse remained above 95 for twelve hours after delivery, and he left the house in considerable anxiety, as he felt that he might be summoned back at any moment. On the sixteenth day after confinement she was seized with a profuse flooding, and it was only after the most persistent efforts on his own part and that of a physician who had been called in, in the emergency, before his arrival that she was revived after the state of extreme exhaustion into which she had fallen in consequence.

Last June Dr. Hanks attended in her confinement a lady who had previously been traveling extensively in the West and South, and had thus contracted malaria. She went through labor perfectly well; but on the fourth day afterward she had a chill. Not being acquainted at that time with the previous history of malaria, Dr. Hanks supposed that she was probably going to have puerperal metritis or peritonitis; but when she told him of this, he felt reassured, and at once gave her a large dose of quinine. The drug was continued for some time, and she had little further trouble. In this case, bromide of potassium was given in connection with the quinine, and it seemed completely to counteract all its unpleasant effects.

Dr. S. S. JONES said that it had fallen to his lot to meet with a great deal of malarial trouble in puerperal women, and he thought that Dr. Barker's admirable paper was exceedingly well timed. There was one point, however, which had not been touched upon in it, and to which he would like to call the attention of the society, as he believed it to be of considerable importance. From a pretty extensive experience in these cases complicated with malarial difficulty, he had become convinced that septicæmia was liable to supervene upon malarial puerperal fever, and he thought that this fact afforded an explanation of those exceptional cases occasionally met with in which the administration of quinine is not followed by the good effects which ordinarily result from its use. As his practice lay principally in a malarial district, the northeastern portion of the city, he had adopted the rule of always giving quinine on the second day after

confinement, because he had now come to regard any case as exceptional in which, without this, there was not some malarial development within the first ten days following delivery. If he found that the malarial manifestations continued after a trial of quinine in sufficient doses, it was his practice to cleanse the uterus thoroughly with a solution of carbolic acid. In such cases this always acted most happily, and in some instances he believed it had been the means of saving life.

He then mentioned particularly one case, in which, notwithstanding the fact that the patient was fully cinchonized, the temperature remained at 105° F., until the cavity of the uterus was treated as above; when it almost immediately went down to 103°, and the procedure being repeated from time to time, it gradually sank to the normal. This, and other cases in which he had repeatedly tried the same thing, seemed to demonstrate a definite relation between the local treatment and the reduction of temperature, entirely independent of the administration of quinine. His experience had been strongly confirmatory, therefore, of the conclusion which, after an interesting discussion, was arrived at in the London Obstetrical Society last year, namely, that a high temperature remaining for any length of time during the puerperal state is very apt to result in septicæmia from the decomposition of blood in the cavity of the uterus occasioned by that high temperature.

Recent Literature.

Pharmacographia: A History of Drugs of Vegetable Origin met with in Great Britain and British India. By FRIEDRICH A. FLÜCKIGER, Phil. D., and DANIEL HANBURY, F. R. S., etc. Second Edition. London: Macmillan & Co. 1873.

This noble work first appeared in 1874, and became at once a favorite with advanced students of materia medica proper (as distinguished from therapeutics). It met with a rapid sale that exhausted the entire supply in a few months, since which time until now, owing probably to the untimely death of Mr. Hanbury, in 1875, it has been out of print, and stray or second-hand copies have been eagerly bought at an advanced price. It was translated into French, in 1878, by Dr. J. L. de Launessan, with the addition of notes and cuts.

It is difficult to find a work covering exactly the same ground as this with which to compare it. We are accustomed to materia medicas written by physicians where therapeutics is the principal object, to pharmacopœias and dispensatories especially devoted to preparations, to pharmaceutical chemistries and medical botanies, but here is a work devoted to the study of drugs as objects for examination and description, without reference to their value or uses. The learned authors, neither of them physicians, one a member of a well-known English drug house, the other an eminent pharmaceutical chemist, have treated the substances which they have selected to describe much as a naturalist would the subjects of his investigations, studying them thoroughly, conscientiously, as it were, for their own sakes; and it is safe to say that the work laid out by these gentlemen was never so well done before. The articles upon opium, cinchona, olibanum,

styrax *liquidus* (as Mr. Rice will have it), and many others are monographs of which any one might be proud.

The most noticeable addition in the present volume is the bibliographical appendix, filling sixteen of the hundred new pages. This is interesting as showing the extended reading upon which the historical part of the work is founded, and is also valuable to any one interested in the subject, as it gives the dates and short accounts of the writers or books referred to. In the body of the book the principal changes are from the nature of the subject in the chemical sections, where the work has been well brought down to the present time: thus the extensive researches of Dr. Wright upon the aconites are embodied here; *caoutchouc*, *neconoiotin*, and alkaloid No 17, *gnoscopina*, are added to the heretofore known ingredients of opium; physostigma is credited with its new alkaloid *calabarina*, and pomegranate-root bark with *pelletierina*. The glucoside of cherry-laurel leaves is now stated to be different from amygdalin, that of bitter almonds. Schmielberg's *digitarin* is added to the confusing chemical substances composing digitalis, and Nativelle's crystallized digitalin is stated to be a mixture. The *veratridia* of Robbins, as well as the *veratroidia* of Bullock and Mitchell, are noticed in the chemical section of the article on veratrum viride. Finally, crystallized *ergotina*, the new alkaloid of ergot, isolated by Taurer, and the *sclerotic acid* of Dragenlorff, with *pirosclerotina* and half a dozen other less important substances recognized within the past year or two, are here described.

The botanical and historical sections are much less changed; still, some new facts and explanations are added, as well as many new references. The Meddygon Myddfai, a collection of medical recipes in use by the Welsh physicians of the thirteenth century, has furnished some of these, and Bentley and Trimen's new Medical Botany some others.

The commercial part, of "unequal value," as the authors acknowledged, in the first edition, does not appear to have received much attention in this, and remains about as before. It is singular that the statement there made concerning the oil of cade, "It is imported from the Continent, but where made and from what wood we know not," should still remain true.

A most serious fault in the book for the American student is its purely British scope. It was designed to illustrate the London and Indian drug market, and to these it is confined; there are a score or more of drugs in the United States Pharmacopœia, of acknowledged utility and extensive use in this country, not to be found in it, the addition of which would have greatly increased its value upon this side of the water.

The new titles in the present edition are, *Folia Pilocarpii*, *Flores Arnicæ* (the root was already in the first), and *Galla Chinensis*.

It is hardly fair to criticize a therapeutic inaccuracy in a book which makes therapeutics no part of its subject, but the statement in regard to digitalis, that it has the "effect of reducing the frequency and force of the heart's action," might be amended with advantage.

In the field which it covers this book has no equal.

The Feigned Insanity of Troy Dye.

The *Sacramento Dental Jurist* for January, 1880, contains an account of the feigned insanity of Troy Dye, by Dr. G. L. Simmons, M. D. Harv., commissioner in lunacy. This case has excited great interest in California from the unusual nature of the crime and the desperate attempt of the murderer to escape its consequences. Troy Dye, a public administrator, planned the murder of several wealthy citizens without heirs, in order to provide fees for his office and to rob their estates. One of the murders was executed by hired assassins, and discovery followed. At the trial Dye acknowledged his guilt, but on being removed to jail for the noon recess fell in a heap on the floor, with a twisting motion, as the jailer said, of the right leg. Physicians were summoned, who agreed that he had been frightened into semi-consciousness, partial delirium, and slight spasm by an overwhelming sense of his inevitable fate.

To avoid execution it is said he continued to feign insanity in various forms. At first he seemed more or less demented, and after an interview with doctors, in which protrusion of the tongue to one side was mentioned as indicating paralysis, he clumsily imitated this symptom. Afterwards he assumed a maniacal condition, and then a mixture of dementia and mania, answering many questions well, but becoming stupid when allusion to his execution was made.

Dr. Simmons, Dr. Shurtleff, of the Sacramento Asylum, and others, testified to his sanity and to the existence of shamming. Dr. Dixon, homœopathist, insisted that he was insane and paralyzed, and that lesions would be found at the origin of the auditory, optic, and facial nerves. After his execution a post mortem was made, at which all the physicians were present. No lesion of any kind was found on the most careful inspection and the brain was as healthy as that of his confederate, Anderson, who was hanged at the same time. There were adhesions of the dura mater along the Pacchionian bodies in both brains, but there was no congestion, or incipient inflammatory symptoms, or slight apoplectic clots, or visible lesions in either. It was agreed on the part of the regular physicians to call it a case of "homœopathic insanity."

A Manual of Pathological Histology. By V. CORNIL and L. RANVIER. Translated, with notes and additions, by E. O. SHAKESPEARE, M. D., and J. H. C. SIMES, M. D. Philadelphia: Henry C. Lea. 1880.

This book, which originally appeared in France in several portions at intervals extending from 1869 to 1876, was very well received abroad, and still maintains a prominent position. It has been translated into German as well as other languages, and now an English edition has appeared, which differs somewhat from the original, as it seemed best to bring some of the older portions of the work up to the views entertained at present. The translators have done their work very well indeed, rendering it into smooth and excellent English, and in their selection of new material they have in the main used good discrimination. There has been a considerable addition to the number of wood-cuts in the original, and though most of them materially aid in elucidating the text, notably the beautiful cuts taken from the second part of the medical volume of the *Medical and Surgical History of the*

War, by Dr. J. J. Woodward, the repetition of a number of them seems hardly called for. The additions are mostly brought in at the end of the subjects, whereas they would be less distracting and answer the purpose better if they were incorporated in their proper places in the text. In the description of the changes in vessels there is less said of the recent work of others besides that of one of the translators than seems desirable, especially in view of the advances recently made in this subject.

We heartily commend the book as one of the best works on the subject. The publisher has done his work remarkably well, and turned out a most attractive-looking book.

The Alienist and Neurologist. A Quarterly Journal of Scientific, Clinical, and Forensic Psychiatry, and Neurology. Edited by C. H. HUGHES, M. D. St. Louis. Vol. I. No. 1.

This new journal is at hand, and presents an attractive appearance. It contains 125 pages of varied matter, including nine original articles by Drs. Curwen, Earle, Beard, Hamilton, Hughes, Dean, Stevens, and Workman. The Propositions of the Association of Superintendents, Neurasthenia, Tendon Reflex, Aphasia, Cerebral Thermometry, Relief in Nervous Diseases following Enucleation of the Eyeball, Syphilitic Hypochondriasis, and the Curability of Insanity are the subjects treated. The selections consist largely of the proceedings of foreign societies, those of the psychological and neurological section of the International Congress at Amsterdam being of special interest. The Editorial is a hopeful survey of the field of psychiatry, and the intention is declared of an endeavor to prevent the divorce of psychology and neurology from the main body of medicine. We wish the new journal all success, and have no doubt it will find its place among the like periodicals of the country.

T. W. F.

A Text Book of Physiology. By M. FOSTER, M. A., M. D., F. R. S. Third Edition, revised. London: Macmillan & Co. 1879.

The third edition of this valuable text-book is now before us. It differs from the preceding edition chiefly in the fact that the section on Muscle and Nerve has been rearranged and to a large extent rewritten. The general character of the work remains unchanged, and fully merits the praise bestowed upon it at the time of the appearance of the first edition.¹ The judicial fairness with which Professor Foster treats all disputed questions, and the care which he has taken to present the results of recent investigations, entitle his work to the highest place amongst English text-books of physiology.

The price of the work has been much reduced. Though larger by 80 pages than the preceding edition, it is offered at \$5.50. It is therefore somewhat difficult to avoid the conclusion either that the former price (\$5.00) was exorbitant, or that the present one cannot be very remunerative. The publishers also announce that a still cheaper students' edition is soon to make its appearance.

¹ The JOURNAL, June 21, 1877.

Medical and Surgical Journal.

THURSDAY, MARCH 14, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, OSGOOD AND COMPANY, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, OSGOOD AND COMPANY, BOSTON, MASS.

THE NEW CODE OF ETHICS OF THE MASSACHUSETTS MEDICAL SOCIETY.

THE new code of ethics of the Massachusetts Medical Society is presented to our readers to-day. This draught, as adopted at the meeting of the councilors of the society held February 4th, is that reported by Dr. Henry J. Bigelow, who formed a minority of one of the committee appointed to consider the subject, and the final action of the councilors is the result of a deliberation extending over two years. The present code may be regarded as a compromise between a more elaborate one and none at all. It is concise and clear, and should suffice to enlighten the understanding, if not to restrain the inclinations, of the poacher, which character is after all, we take it, the exciting cause of most codes. That the species is not extinct, a communication in our last issue appears to show. For our own part, we should have preferred to have struggled on as have our predecessors, without such an instrument; but, if these things must be, we again regret that some uniformity cannot be secured for the country at large. This feeling, however, need not carry us so far as to desire the adoption of the fine old-fashioned code of the American Medical Association, of the presence of whose pompous and ponderous garrulity at the end of the volumes of Transactions most men are sufficiently aware to enable them to turn off in time down a side page, thereby making a mistake at least once, for if read with care and discrimination this compilation is by no means dull. The physician who may hitherto have shunned it will do well to read it, and still better to commend it to his patients. He will then imbue his mind with the greatness of his mission, and study to unite tenderness with firmness and condescension with authority, thus inspiring their minds with gratitude, respect, and confidence. They will learn that, having once selected him, they should always apply for advice, even in what may appear trivial cases, for on the slightest accidents the most fatal results often supervene; that their own crude opinions as to the fitness of his prescriptions should never be permitted to interfere with their attention to them, for a failure in one particular, even as to diet, drink, or exercise, may render an otherwise judicious treatment dangerous, perhaps fatal; and that after recovery—or, we suppose, if they have indulged their own crude opinions, equally after death—they should entertain a just and enduring sense of the value of his services, which are of such a character that no mere pecuniary acknowledgment can repay or cancel them. Let them be

warned, however, not to interpret the latter part of this clause too seriously. Both physician and patient will learn many other things if they will be advised and inspect this megatherium of a by-gone period.

To the members of the profession in Massachusetts we wish a pleasant journey under the auspices of the compact little code which is appended, and hope it may prove a pillar of fire to the ignorant Israelite, and a Red Sea to the false Egyptian.

CODE OF ETHICS OF THE MASSACHUSETTS MEDICAL SOCIETY.

(Adopted by the Councilors, February 4, 1880.)

Object of a code of ethics. The Massachusetts Medical Society is designed to secure to the public a body of well-educated and otherwise trustworthy physicians. Its code of ethics is intended to furnish certain principles and rules of action for their guidance and convenience.

I. The relation of the physician to medical science. A physician should lend his influence to encourage sound medical education, and to uphold in the community correct views of the powers and the limitations of medical science and art.

II. The relation of the physician to medical business. The professional success of a practitioner depends upon qualities connected with his moral character, his scientific attainments, and also his industry and business talent. But the relation of practitioners of medicine to families and households is not like that of tradesmen to their customers. The kind of competition which might be considered honorable in business cannot exist between physicians without diminishing their usefulness and lowering the standing of the medical profession. (See IV. § 1; V. § 1.)

III. The relation of the physician to his patients. The first duty of the practicing physician is to his patient, who has a right to expect that his disease shall be thoroughly investigated and skillfully treated, with charitable consideration for his mental peculiarities or infirmities, and in a relation strictly confidential.

1. The physician should not make unnecessary visits. He should neither permit needless apprehension, nor fail to give reasonable notice of danger.

IV. The relation of the physician to other practitioners and to their patients. In his relations with another medical practitioner and his patients, a physician should be governed by strict rules of honor and courtesy. His conduct should be such as, if universally imitated, would insure the mutual confidence of all medical practitioners.

The foregoing rule should be a sufficient guide of action. Some of the following contingencies will illustrate its application:—

1. A physician should take no step with a view directly or indirectly to divert to himself the patient or practice of another physician.

2. If formally requested to assume charge of a patient or family usually attended by another physician, he should consent to do so only after notifying the latter,—unless the case be one of pressing necessity.

3. If a physician is called to a patient during the temporary absence or illness of the usual physician, or in case of accident or other emergency, he should direct that the former be sent for as soon as he is able to take charge of the case, and should then relinquish it to him. It is generally agreed that, among sev-

eral physicians thus called, he who first arrives shall act, unless the family designate another.

4. A communication from the temporary to the usual physician, in the absence of the latter, should be written and sealed, and not simply verbal.

V. The relation of the physician to quackery. In every community there are minds naturally inclined to quackery, which has flourished in every age. It grows by being noticed, and thrives best under opposition. It is commonly unwise to employ argument against it. But a physician should lend his influence to establish a distinct line between the regular practice of medicine and the practice of quackery, and should avoid any act which might tend to weaken such a distinction either in the professional or in the public mind.

1. Thus, he should not consult with an irregular practitioner (see *By-Laws*); nor countenance the use of secret remedies; nor be interested in medical trade-marked preparations; nor give certificates recommending mineral waters, patents, or medical preparations, or the like; nor give a commission to an apothecary, nor receive one from him; nor advertise himself or his practice in public print; nor publicly advertise advice or medicines to the poor, etc.

VI. Consultations should be encouraged in cases of unusual responsibility or doubt.

A consultation is called for the benefit of the patient, and to give him the advantage of collective skill. Should there be a difference of opinion, discussion should be temperate, and always confidential.

A consulting physician should be careful to say or do nothing to impair the confidence of the patient or his family in the attending physician.

1. See, for guidance of a consultant, IV. §§ 1, 2, 3, 4.

2. At a consultation punctuality is important; and non-arrival within fifteen minutes after the appointed time should be interpreted as non-attendance.

3. For the advantage of the patient and for economy of time, it is well in a consultation to observe a certain order of business. The following has been found convenient:—

The attending physician, having stated in general terms the nature of the case, may then call, in turn, upon each consultant, if there be more than one, to examine the patient,—the usual order being that of seniority. No consultant should make an examination or inquiry out of turn. On retiring, the attending physician may invite, in the usual order, the opinion of each consultant, who should not be interrupted while giving it; after which he may add his own. In conclusion a course of action may be agreed on, or the attending physician may be left to act at his own discretion.

VII. Fees. A fee-table has a local application, and is designed to indicate a fair or average amount due for services. But if the patient fully understands it beforehand, a physician is at liberty to place any value he sees fit upon his services. It is then at the patient's option to decline them or to pay the price. A physician should be considerate of the poor.

1. A patient in moderate circumstances should not be called on to pay a fee unusually large for the service rendered, without a previous explicit understanding. A physician, if able, should offer to pay the medical attendant of himself or his family. Unless by special agreement, a physician attending or acting for another should receive the fees. Among obstetricians a rule obtains that the interval between the birth of the child and of the placenta halves the service and the fee. A fee should be charged for a medical certificate or paper of value to the applicant,—connected, for example, with absence or exemption, life insurance, pension papers, etc., except the usual certificates of vaccination and death.

VIII. Seniority. Seniority applies rather to duration of practice at the place in question than to age.

LUNACY REFORM.

It will be remembered that a meeting was held at the Cooper Institute in New York last December for the purpose of considering the interests of the insane. At this meeting resolutions were adopted which stated substantially that the system of asylum management was defective: that a lunacy commission, modeled on the plan of the English commission, was needed for New York; and that a committee should be appointed to devise plans for the organization of such a lunacy commission, and to present to the next legislature a bill for its creation. A committee was accordingly chosen, consisting of Messrs. Wm. C. Church, Dorman B. Eaton, and Chas. E. Whitehead, and Drs. Geo. M. Beard and E. C. Seguin. This committee have now prepared a bill, a copy of which has been sent us, together with a full explanation and a letter appended by Mr. Eaton, on Changes in the Present Lunacy Laws of New York, written and published in December last.

The bill first provides for an addition of three members to the State Board of Charities. Two of these members shall be physicians, and shall have practiced ten years in the State, and the other member shall be a lawyer who also has practiced ten years in the State. After the appointment of these officers the State Board of Charities shall be the State Commissioner in Lunacy, and have all the authority now conferred on the state commissioner, and these powers shall be exercised through an agent or secretary. Particular attention is to be paid to making an annual report, which shall contain suggestions for the improvement of lunacy administration. The secretary to be appointed shall be a competent and experienced physician, and not a member of the board, and shall perform any duties assigned him by the board.

Such is in brief the bill. For the first time, those persons who are seeking to institute asylum reform may hope to see some definite results growing out of their efforts; for, instead of trying to tear down insane asylums with iconoclastic hands, they moderately ask for what any citizen may with reason expect to have. All asylum superintendents of integrity will unite with them in asking for thorough asylum supervision, for it will bring the public and themselves into clearer and friendlier relations. As the committee say in their "brief explanation," "reforms are most promoted by moderate measures in the right direction." The committee believe in a lunacy commission, but are willing to use the State Board of Charities as a stepping-stone.

We do not wish to criticise the bill in any but the most friendly spirit, as we feel that it will, if passed, result in lasting good to the public, but we wish to present one or two objections that have occurred to us. It will first be seen that the members who are to be added to the board are not required to have a knowledge of insanity or insane asylums. We think this a mistake, for intelligent and thorough supervision of asylums can be efficiently undertaken only by experts. Insanity in its social and clinical relations should be practically understood, and still more

the practical management and treatment of the insane in the asylum. No man would be intrusted with the management of a business without practical acquaintance with its details, and to no greater an extent is a physician without special experience competent to pass upon the needs and care of the insane. We know that many persons imagine themselves to be possessed of a thorough understanding of insanity, and they therefore are inclined to ignore the knowledge of the person drilled in its treatment, and to assume that any one is competent to undertake the management of the insane, but our experience has taught us that such is not the case. We have seen earnest attempts made at lunacy reform, but its advocates have so magnified the smallest evils, misinterpreted facts, and erred in their methods of conducting the reform that they have injured rather than helped their cause.

While commending the moderation in the construction of the bill, we have gained the impression that the direct inspection of the asylums must still be chiefly left to the secretary. He, as the agent of the board, will visit and investigate the asylums, while the new members, serving without compensation, can of necessity give but a more or less limited portion of their time to the work, and must therefore rely for information on their secretary. It would have seemed better to us to enlarge the membership of the board, give it the same powers asked for in the bill, and, instead of specifying the employment of a secretary to have left the board the power to appoint such inspectors or commissioners as, in their judgment, might seem best.

The end of the efforts being made this winter in New York will eventually be a paid lunacy commission, but until public opinion recognizes the importance of such a change, reformers, looking only to the true and highest interests of the insane, must be satisfied slowly to fight their way with discretion and patience.

STONE IN THE BLADDER: LITHOLAPAXY.

THE following article appeared editorially in *The Lancet*, February 7th:—

The universal testimony of experience approves the well-known dictum that every foreign substance that gains admission into the living body, or that is engendered within it, no matter what its origin or its nature, must become organized or absorbed, eliminated or encysted, if it is not more or less seriously to prejudice health or to destroy life. In one or other of these modes does nature endeavor to preserve and protect living tissues from violent reaction, disorganization, and death. Not un seldom, however, she signally fails, and has to call in the aid of art. No better illustration of this can be adduced than that of stone in the bladder. If the peccat' substance be over a certain size, nature's unaided efforts are ineffectual to procure relief. Organization of a vesical calculus is impossible, absorption doubtful, elimination rare and uncertain, encystation accidental, painful, and

hazardous. Surgery alone may be trusted to act intelligently and safely. This truth has long been recognized. The earliest records of the surgical treatment of stone in the bladder belong to times now very remote. The operation of cutting for stone is one of the oldest in history, and reigned for at least two thousand years without a rival. Its supremacy remained unquestioned until the beginning of the present century, when the practice of crushing through the urethra was introduced. Then for fifty years crushing steadily grew into more and more esteem, and the reputation of cutting dwindled in a corresponding degree, till at length the more sanguine advocates of lithotripsy confidently prophesied the final abandonment of lithotomy as uncalled for and unnecessarily severe. In the opinion of cooler minds, however, the ultimate triumph of lithotripsy was not so sure. Little by little the uncompromising lithotritists had to change their position; the cutting and the crushing operations were no longer antagonistic but complementary, provided always that lithotripsy was to be the rule and lithotomy the exception. With this avowed lithotripsy lost much of its prestige, and was not likely again soon to recover its old status. Its good name had been called in question, and there were those who were not slow in dragging to light some of its drawbacks and disadvantages. Every year the advocates of the newer operation had to make more and greater concessions to the champions of the older, and, in spite of the oft-repeated unparalleled results of the professed lithotritists, a distinct reaction began some two or three years ago to set in towards the cutting operation. About that time, however, an unexpected event occurred which called off attention into another direction. Professor Bigelow, of Harvard, United States, proposed and introduced an entirely new method for the removal of stone from the bladder, namely, by complete crushing and continuous evacuation of the fragments by means of aspiration. This method he designated "litholapaxy."

We have called Professor Bigelow's method an entirely new one, and such we believe is its true character, notwithstanding the attempts that have been made to explain away its significance or to destroy its originality. Litholapaxy can appear as a mere modification of lithotripsy only to a superficial observer. The philosophical student will not fail to discover an essential and fundamental difference of principle. Apart from the irreconcilably opposite modes of procedure, in crushing a stone after the manner of professed lithotritists, and in removing it by Professor Bigelow's plan, there is no real analogy whatever. Lithotripsy, as ordinarily practiced, is an operation of least interference: the calculus is crushed at one sitting or at many sittings into fragments small enough to be passed, *per vias naturales*, by the expulsive efforts of the bladder and abdominal muscles. In other words, a rude attempt is made to reduce a large calculus into several small ones, which may be passed spontaneously. Litholapaxy, on the other hand, is a radical operation, and aims at breaking up the whole of the calculeous mass, and removing it at once by powerful

but systematic aspiration. In the one the calculus is broken, and then nature is left to get rid of the irritating fragments as best she may; in the other the comminution and the removal are alike accomplished by mechanical means. It is in vain that efforts are made to establish identity between the aspirator employed for the entire removal of all the fragments of stone in the operation of litholapaxy and the weak and inefficient suction-bottles made use of to remove the finer *débris* in the operation of lithotripsy. One frees the bladder from all foreign matter; the other removes only the soft pulverulent particles, and allows the larger, hard, and angular fragments to come into closer and rougher contact with the mucous membrane lining the interior of the bladder.

In the interests alike of science and humanity it is right that these important truths should be distinctly and emphatically stated. Almost every observer who has recorded his experience of Professor Bigelow's method has made confession of a preliminary repulsion which only success in application has modified or removed. The plan is still on its trial, though so far eminently satisfactory. Those, on the other hand, who had the largest opportunities of using the suction-bottle for the removal of the finer *débris*, after ordinary lithotripsy, were almost unanimous in asserting that, as a rule, it was better to do without it. And probably this apparent paradox may, after all, contain a kernel of truth. It is not difficult to conceive that unless all fragments can be removed it is better to let the pulverulent matter remain behind, as a soft pulsatious sediment to protect the tender walls of the bladder from actual contact with the large and sharp fragments that cannot pass through the small tube that is used in Crampton's or Clover's bottle. This may be the true but hidden reason why the suction-bottle was not approved by the best lithotritists, and it may likewise afford a clue to the success of Professor Bigelow's bold and ingenious device.

THE DUTY ON QUININE.

THE House Committee on Ways and Means have given a hearing to manufacturers of quinine who desire the duty on the imported article technically known as sulphate of quinia, which was removed by act of Congress during the special session, to be restored. Several manufacturers of sulphate and other salts of quinia made arguments before the committee in support of their memorial. The points made were that the law removing the duty was hurriedly passed through Congress, without giving them an opportunity to be heard; that it went into immediate effect, affording them no opportunity to prepare for the change; and that while the duty on imported quinine has been removed the articles from which it is manufactured are still taxed, fusel oil paying a duty of two dollars per gallon, alcohol one dollar and seventy cents per gallon, soda ash one quarter cent per pound, and cinchona bark ten per cent. *ad valorem*. To offset these duties and taxes they argued that a duty should be imposed upon foreign sulphate of quinine, to enable

them to compete with foreigners, whose governments guarded their interests most carefully, and who have, in consequence, great advantages over American manufacturers. They also presented a memorial, numerously signed by the druggists and dealers of forty-eight cities in various parts of the country, favoring an import duty on foreign quinine of at least ten per cent. *ad valorem*. The memorial sets forth that the continued manufacture of sulphate of quinia in this country is a matter of great consequence to the people at large; that the American article is uniformly of excellent quality and superior to imported, and should, as a matter of policy, be protected. A large number of letters from physicians and druggists were also offered as cumulative testimony to the statements set forth in the memorials.

As we have before said, there are two sides to the "free quinine" question. In 1878 the price of sulphate of quinia was \$4.50 per ounce; in 1879, after the removal of the ten per cent. duty, it fell to \$2.60 with a small demand, rising again in 1880 to \$3.40. Our best manufacturers have always maintained a high standard, and it is questionable how far the public are benefited by the importation of poorer qualities at prices with which the home manufacturers cannot compete. It must be borne in mind, however, that the removal of the duty is to a great extent a protection against the artificially high prices which have at times been brought about through speculation.

HEALTH OF LARGE ENGLISH TOWNS.

The *Lancet* states that the severe cold of the third week in January caused a further marked increase of mortality. In twenty of the largest English towns, estimated to contain in the middle of this year seven millions and a half of persons, or nearly a third of the entire population of England and Wales, 5110 births and 4264 deaths were registered during last week. The births were 75 below, whereas the deaths were no less than 989 above, the average weekly numbers during 1879. The deaths showed a further increase of 523 upon the numbers returned in the two preceding weeks, and the annual death-rate, which had been 24.2 and 26.0 in the two previous weeks, further rose last week to 29.7. The lowest death-rates in the twenty towns last week were 16.5 in Wolverhampton, 21.0 in Portsmouth, 21.4 in Sheffield, and 24.1 in Bradford. The rates in the other towns ranged upwards to 31.3 in London, 31.7 in Liverpool, 32.0 in Plymouth, 32.3 in Salford, 31.9 in Manchester, and 35.2 in Liverpool.

The deaths in the twenty towns referred to the seven principal zymotic diseases, which had been 519 and 514 in the two previous weeks, further rose last week to 600; they included 273 from whooping-cough, 127 from scarlet fever, 110 from measles, and 39 from fever, principally enteric. Whooping-cough showed the largest proportional fatality in Salford, Plymouth, and London; measles in Hull, Plymouth, Nottingham, and Leicester; and scarlet fever in Norwich and Sunderland. Of the 17 deaths referred to diphtheria in

the twenty towns, 10 occurred in London and 3 in Birmingham. Small-pox caused 12 more deaths in London and in its outer ring of suburban districts, but not one in any of the nineteen large provincial towns. The fatal cases of small-pox in London were more numerous than in any week since the beginning of July last. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 75 and 84 at the end of the two preceding weeks, were 80 on Saturday last; during the week 22 new cases of small-pox were admitted to these hospitals, against 8 and 21 in the two previous weeks.

Our weekly Mortality Tables, which we are enabled to print through the kindness of the Secretary of the Massachusetts State Board of Health, indicate the continuance of a high death rate in Great Britain.

MEDICAL NOTES.

— Surgeon-General William Maxwell Wood, United States navy, retired, died lately at his residence at Owing's Mills, Baltimore County, Md., in the seventy-second year of his age. Dr. Wood was born in Baltimore, and entered the navy in 1829 as an assistant surgeon. He saw a great deal of sea service early during his career; in 1844-46 was fleet surgeon of the Pacific squadron. During this period Commodore Sloat, commanding the Pacific squadron, wrote a letter to him, saying, "I am most happy to acknowledge the very important services you rendered the government and the squadron in the Pacific under my command at the breaking out of the Mexican war. The information you furnished me at Mazatlan, from Guadalajara, at the risk of your life . . . induced me to proceed immediately to California, and upon my own responsibility to take charge of that country. I have always considered the performance of your journey through Mexico at that time as an extraordinary feat, requiring great presence of mind and address. How you escaped from the heart of an enemy's country and such a people has always been a wonder to me, and has been so characterized on all occasions." The chairman of the Senate Naval Committee also complimented Dr. Wood upon his success in furnishing the information upon which the acquisition of California was based. In 1856-58 Dr. Wood was attached to the East India squadron, and took part in the Chinese war. During the civil war he was fleet surgeon of the North Atlantic squadron. He was chief of the Bureau of Medicine and Surgery in 1870, and in 1871 was retired.

— We wish again to call the attention of our readers to the *Index Medicus*, now entering upon its second year. It has admirably fulfilled its purpose, and as this publication in no wise conflicts with any medical journal, either local or special, but on the contrary actually forms a guide and supplement to all, it would seem that an appeal for coöperation in its behalf should meet with some practical and cordial response from its contemporaries and their subscribers.

— Says the *Medical and Surgical Reporter*: "A

physician of this city recently informed us of a case in which he had performed vaccination on a child, followed in a few days by the usual signs of a successful result. On the seventh day, however, the child was attacked with varicella; the redness, etc., disappeared around the vaccinated surface, and all signs of irritation passed away. On the fourteenth day, the varicella having run its course, renewed signs of the vaccine impression began, and a perfect vesicle was formed, following the usual course. Thus the virus had lain dormant in the system during the presence of the acute disease. Can similar instances be furnished?"

— Paul Broca has been elected a life senator in the French senate. Paul Bert and Clemenceau are also senators, but in spite of their well-known ability the *Union médicale* says of them, "The two united heads of Bert and Clemenceau are not worth the single encyclopedical head of Broca."

NEW YORK.

— The Rev. Edward Cowley, of "Shepherd's Fold" notoriety, has been found guilty of misdemeanor, as charged in the first indictment against him, namely, "Having the care and custody of a child, to wit, Louis Victor, did wilfully cause such child to be placed in such a situation that his life was endangered, and his health injured." At the last monthly meeting of the Society for the Prevention of Cruelty to Children, a committee was appointed to obtain subscriptions to a fund of fifty thousand dollars to establish a nursery in a suitable building, where the offices of the society may also be located.

— The commencement exercises of the University Medical School were held at the Academy of Music, on the evening of February 17th, when the degree of M. D. was conferred on one hundred and eighty-nine graduates. Among the candidates who received honorable mention for the excellence of their examinations was a son of Prof. Wm. A. Hammond. The ninth annual dinner of the Alumni Association of the college came off at Delmonico's on the 19th, and on this occasion Dr. St. John Roosa, the president, in speaking of one of the objects of the association said: "It is in the air that medical education is undergoing reform. The increased number of instructors, the more thorough examinations, and the better character of the students indicate this. But these are changes without support, and which may not be maintained. There is still wanting radical and organized reform. We still need the community at our back. There is as yet no interest in medical colleges at all commensurate with their importance to the State. This is more true of New York than of Boston or Philadelphia. These medical colleges have the aid of the most influential and wealthiest citizens, while here they are kept alive almost entirely by their teachers."

— In reporting upon the Blackwell's Island asylum, the committee mention first the removal of the former superintendent for incompetency upon their recommendation, and then go on to say that under the reforms instituted by Dr. A. E. MacDonald, by

whom he was supplanted, it bids fair once more to be free from defects. After referring to the increased comforts provided for the patients, and the great diminution in the amount of stimulants consumed, which Dr. MacDonald has made, they state that more nurses have been and are being provided, so that there will be one day nurse to each fourteen patients, and at night one nurse to each ward; and the system of watchers has been so regulated that the new nurse comes on duty one hour before the old one relinquishes her charge, thus affording a conference in regard to the condition of the patients. Work-house women now have been dispensed with, so that the evil contact of these persons with patients has been done away with. A much-needed reform was the establishment of a proper hospital ward, and this has been accomplished by Dr. MacDonald, who found all the sick patients huddled together in damp basement rooms. In regard to the death of the woman Ottner, whose decease followed the assault of another patient, they say, "We have determined, after careful examination, that in no way are the medical officers responsible for this woman's death, but that it occurred as the result of the unavoidable overcrowding. The patient was violent and noisy, and removal to the retreat was therefore a perfectly proper measure. Death by violence in asylums must sometimes occur, in spite of all precautions, and the reports of the best American and foreign hospitals for the insane are by no means free from record of homicidal and suicidal violence." Then, mentioning the methods of restraint in present use, the report continues, "We deem it wise to allude to these simple methods of restraint, or rather protection, which are used only to prevent the patients from injuring themselves, and not in the way mentioned by unjust and censorious critics. Without their use we believe that such accidents as fractured ribs, broken limbs, and an unnecessary expenditure of physical strength upon the part of the patient himself would be disagreeable alternatives, which will be appreciated when the character of these patients is taken into account. The use of restraint, we are pleased to say, has been reduced by Dr. MacDonald fully one third." The report concludes with the following suggestions: *first*, that new buildings or wings be provided at both Wards and Blackwell's islands for the accommodation of the chronic insane; *second*, that the salaries of the assistant physicians be increased, and that two more assistant physicians be appointed for each asylum; and, *third*, that all *Eugene* periodicals devoted to mental and nervous medicine be subscribed for and provided for the asylums.

—Mr. J. S. Browne, lately of the Astor Library, has been appointed assistant librarian of the New York Academy of Medicine, with a salary of one thousand dollars, and the efficiency of the library will no doubt be very greatly increased in consequence of this step. By the liberality of Mr. John Jacob Astor, a very large addition is now about to be made to the Astor Library building, which will correspond in size and appearance to the south section, which was the original structure erected by the present Mr. Astor's

grandfather. The north section, which was built by his father, Wm. B. Astor, will henceforth be the central portion, and in order that a long monotony may be avoided in the three sections this will be provided with an additional story, of a Mansard pattern, while other improvements will be made both in the interior and on the exterior of the building. The entire cost of the addition and improvements will reach two hundred thousand dollars, and the shelving capacity of the library will thereby be increased by two hundred and fifty thousand volumes.

—Mr. James Lenox, the founder of the "Lenox Library," has just died at the advanced age of eighty-nine years. He was also the originator of the Presbyterian Hospital, to which he gave not only land valued at two hundred and fifty thousand dollars, but an endowment fund of another two hundred and fifty thousand dollars.

CHICAGO.

A New Medical College,—What is it?—Steps have been taken by a few of the stirring spirits in all the so-called schools of medicine in Chicago to organize a new medical college, to be called the "Union" school. Its faculty, as so far indicated, is to contain men who have heretofore been known as regular physicians; it will have eclectic doctors and homeopaths, and possibly representatives from one or two other 'pathies. Certainly the right to its name will not be questioned. The talk is of having it located on the "north side." It is intended that a dental school shall be one of its several departments.

Miscellany.

THE PROPOSED LAW TO REGULATE THE PRACTICE OF MEDICINE IN MASSACHUSETTS.

MR. EDITOR.—This bill comes from the Social Science Association. Though the word "quackery" is not mentioned in it, the object of it is to make the public protect itself against quackery in medicine by trying to regulate practice. The word quackery has no definite meaning in the public mind, and it is not possible to give a definition which will be understood and accepted. It is an indefinite term, the meaning of which varies with each person who uses it.

The *Boston Advertiser* says, "A Thompsonian or a hydropathic physician who has learned by experience how far his system is useful, who employs it only so far, and who when baffled tries remedies which his experience or his reading of medical books suggests, or candidly advises his patient to call in another doctor, is not a quack." It is easier to say what it is not than what it is. But the bill must be to protect people against some definite act or persons. In the public mind the only thing that stamps a man as a quack is, not that he is culpably ignorant, but that he is culpably dishonest, and against such it is willing to protect itself.

No one nowadays carries his son to a king to be touched for scrofula, nor hangs the image of a malign

nant tumor on the shrine of a saint to be cured by him; but people still carry their children to Indian medicine men to be cured of hip disease, and bring to people suffering from cancer the remedies put up by those who offer to cure it. Educated people still believe that a man without knowledge of any kind can possess a mysterious tact and faculty for healing. The proofs in their minds are abundant. Innumerable testimonials can be collected from perfectly honest people that they have been cured of every curable or incurable disease. The majority of intelligent men do not think it necessary to protect themselves against people whom they believe to be honest. They go farther than this. The popular feeling is expressed in the *Boston Daily Advertiser*: "It a harsh measure at the best to forbid a man to exercise a calling which others may freely engage in, and to take away his sole means of earning a livelihood, and it should apply only to those whose system is a pretentious fraud." This sounds very well, but who is to decide what a pretentious fraud is? The board of examiners, as proposed by the new bill, has nothing to do with the suppression of fraud.

This board of examiners is the key-stone of the new plan, and is in itself a compromise between what the public know as the different schools of medicine. It is to decide who are prepared to practice medicine, while in the profession the diploma of the Harvard Medical School will be worth more than the decision of the board, which is merely a legal form that every new practitioner of medicine will have to comply with. The members of the proposed board are not to be professors who know by experience how to examine a candidate, but members of what are called the "state societies," appointed by the governor, and who are likely to have forgotten many things that the candidates will know. Such a bill is likely to be an indirect support to second-rate medical schools; for where will be the incentive to give a thorough medical education to men, if their final examination is not to correspond with their education.

What result is such a bill likely to have? It may oblige a few of the present quacks, whom it wants to get rid of, to go somewhere else, but their places will be filled by others who have licenses, and who will pander to the public belief in and desire for the marvelous in medicine with as little scruple as their predecessors, and with a greater appearance of knowledge, and who will be able to hold up to the public their "permit to practice medicine" as a guarantee that they are considered reliable men by the State.

The members of the Massachusetts Medical Society, who want the public to understand that they are simply physicians, and are neither allopaths, nor homœopaths, nor eclectics, and who consider the assumption of any medical dogma as derogatory, are asked to join with what are called by the public "the different schools" to form a supreme board of examination. By doing so the Massachusetts Medical Society will be considered by the public as recognizing that such schools really exist in the science of medicine, and are not merely devices for securing practice. No legislation can do what is the slow work of time and education. Moreover, who is to prosecute? Who is to pay the expenses? Will a jury be found which will convict any one of quackery in any case that cannot at present be brought up into court under the charge of obtaining money under false pretenses? The object should be, not so much to punish the quack, whom the public

believes to be honest, and to be gifted with a wonderful tact in curing disease, as to enlighten the public by exposing him. X.

DEATH FROM IMPACTED GALL-STONES.

BY ISAAC F. GALLOWAY, M. D., LYNN.

CASE I. Fatal obstruction of the intestine by gall-stones is a sufficiently rare event to make the following cases worthy of being put on record.

I was called on the 5th of April to see Mrs. M., a lady sixty years of age, who had then been suffering from biliary colic for three days, during which time there had been vomiting, obstinate constipation, notwithstanding the use of powerful cathartics, and at short intervals paroxysms of severe pain. She stated that she had previously suffered several attacks like the present, but of less severity. At the time of my first visit there was tympanites, stercoraceous vomiting, marked prostration, and pain that only full hypodermic injections of morphia could relieve. Without mentioning details, it is sufficient to say that these symptoms continued until the 11th, when the patient died of exhaustion and inanition.

At the autopsy an ovoid gall-stone was found, measuring $3\frac{1}{4}$ by $3\frac{1}{4}$ inches in circumference, impacted in the small intestine, at a distance of eight feet from the pylorus. It was externally of a dark brown color, and on section exhibited the appearance of pure cholesterine. That portion of the intestine that had been traversed by the calculus was dilated to the size of the colon; the remainder was contracted to one third its normal size. There were a few old adhesions, and the appendix cæci, which was six inches in length, was attached to the fundus of the gall-bladder.

CASE II. The history, symptoms, and progress of this case were similar to those in the case of Mrs. M. The patient was a woman forty years of age.

At the autopsy the intestines and omentum were found matted together and bound down by old adhesions, so as to make it difficult to trace the natural divisions. A stricture was found in the sigmoid flexure tightly plugged by a gall-stone about the size of a pigeon's egg.

PERMANENT CLOSURE OF THE PALPEBRAL APERTURE.

MR. EDITOR, — I am always interested in reading the *Boston Medical and Surgical Journal*, and it is especially interesting to me when it contains a paper by my friend, Dr. Henry W. Williams, on a moot ophthalmological point, such as is that which he has lately read, and which you have published in your issue of the 22d of January. In the discussion thereupon, at page 85, I see that Dr. F. P. Sprague said that Mr. Critchett had advocated, in some cases, the destruction of the conjunctiva, and the consequent and final approximation and closing of the palpebral aperture. I am glad, and am not surprised, if he has done so, for my experience of the operation, in particular cases, is more and more in its favor. I think I have probably done it more frequently than any other ophthalmic surgeon, and as the operation is now so highly commended in America, as well as in England, I wish to retain the credit of its origination. My papers on the subject appeared in the *Lancet* on the 15th and 22d of June, 1872, at pages 821 and 855. I am, sir, your obedient servant.

J. F. STREETFIELD, F. R. C. S.

ROYAL LONDON OPHTHALMIC HOSPITAL, February 16, 1880.

REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 28, 1880.

Cities.	Population estimated for July, 1879.	Reported Deaths in each.	Deaths under Five Years	Percentage of total Deaths from

Two thousand four hundred and thirty-two deaths were reported; 927 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 433, consumption 397, lung diseases 361, diphtheria and croup 155, scarlet fever 70, measles 51, diarrheal diseases 41, typhoid fever 33, whooping-cough 33, erysipelas 19, malarial fevers 16, cerebro-spinal meningitis nine, small-pox six. From *measles*, New York 28, Philadelphia nine, Brooklyn and Chicago three, New Orleans and New Haven two, St. Louis, Cleveland, Lawrence, and Holyoke one. From *whooping-cough*, New York and St. Louis five, Brooklyn, Boston, and Cincinnati three, Chicago, Baltimore, Cleveland, and Charleston two, New Orleans, District of Columbia, New Haven, Cambridge, Gloucester, and Fitchburg one. From *erysipelas*, New York seven, Philadelphia, Chicago, and Milwaukee two, Brooklyn, St. Louis, Baltimore, Cleveland, Providence, and Worcester one. From *malarial fevers*, New York seven, Brooklyn, St. Louis, New Orleans, and Milwaukee two, Baltimore one. From *cerebro-spinal meningitis*, Chicago two, New York, Baltimore, New Orleans, Cleveland, Fall River, Malden, and Quincy one. From *small-pox*, Philadelphia five, Baltimore one. One hundred and sixty-four cases of measles, 38 of diphtheria, 31 of scarlet fever, four of whooping-cough, and three of typhoid fever were reported in Brooklyn; 18 of diphtheria and 10 of scarlet fever in Milwaukee; scarlet fever 40, diphtheria 17, typhoid fever two, in Providence; diphtheria 37, scarlet fever 13, in Boston; diphtheria five, scarlet fever one, in Cambridge; diphtheria nine, scarlet fever seven, in New Bedford. The death-rate of whites in District of Columbia was 23.72, of colored 42.71.

The total number of deaths and of deaths under five reported is very nearly the same as for the previous week. Lung diseases remained about as before, and the mortality from consumption was a little greater. There were fewer deaths from typhoid and malarial fevers, the other infective diseases remaining without noteworthy change. In 28 cities and towns of Massachusetts, with an estimated population of 1,032,460 (pop-

ulation of the State about 1,690,000), the death-rate was 21.26 against 20.22 and 22.09 of the previous two weeks, with an increased mortality from scarlet fever and diarrheal diseases.

For the week ending February 7th, in the 20 chief Swiss cities and towns, diphtheria, scarlet fever, and typhoid fever were the only prevalent infectious diseases, the latter two, however, not having proved very fatal; there were no deaths from small-pox or measles; lung diseases continued to cause excessive mortality. In Belgium, small-pox was more fatal, 46 deaths in seven towns having been due to it; bronchitis, pneumonia, diarrhoea, and whooping-cough were excessively prevalent and fatal; croup and typhoid fever quite so, while scarlet fever and measles caused only a moderate number of deaths. In Paris, Lyons, and Marseilles the death-rates were enormous, due largely to the great fatality of small-pox, typhoid fever, diarrhoea, and acute lung diseases. In 142 German cities, with an estimated population of 7,602,749, the death rate was 26.9 against 25.7 of the previous week. Three thousand nine hundred and twenty-eight deaths were reported; 1739 under five years; pulmonary consumption 594; acute diseases of the respiratory organs 487, diphtheria and croup 158, whooping-cough 64, typhoid fever 57, scarlet fever 55, measles and *röteln* 36, prurient fever 28, small-pox (Dantzig, Berlin, Beuthen, Stargard) 4, typhus fever one. The death-rates ranged from 16.1 in Wiesbaden to 41.9 in Erfurt; Königsberg 32.0; Dantzig 32.3; Breslau 28.4; Munich 36.4; Dresden 22.4; Berlin 23.5; Leipzig 24.8; Hamburg 24.5; Hanover 21.0; Bremen 29.2; Cologne 33.0; Frankfurt 20.7.

For the week ending February 14th, in the 20 English cities and towns, with an estimated population of 7,499,468, the death rate was 30.1 against 37.0 of the previous week. Four thousand three hundred and twenty-three deaths were reported. Lung diseases had very much declined from 1557 to 1020, but exceeded the corrected weekly average by 554; whooping-cough 279, scarlet fever 110, measles 81, fever 52, diarrhoea 32, diphtheria 20, small-pox (London) 12. The death-rates ranged from 19.3

in Leeds to 35.5 in London; Bristol 24.7; Birmingham 23.1; Leicester 19.7; Liverpool 29.9; Manchester 26.1; in Edinburgh 19, Glasgow 23, Dublin (small-pox, three deaths) 45.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM FEBRUARY 28, 1880, TO MARCH 5, 1880.

COOPER, GEORGE E., lieutenant-colonel and assistant medical purveyor. To be relieved, temporarily, in the charge of the medical purveying depot in San Francisco, Cal., by Captain H. Johnson, medical storekeeper. S. O. 48, A. G. O., March 3, 1880.

HEGER, A., major and surgeon. Having reported in compliance with orders from the A. G. O., is assigned to temporary duty at department headquarters. S. O. 42, Department of Texas, February 26, 1880.

MUNN, C. E., captain and assistant surgeon. Granted leave of absence for one month. S. O. 44, Department of the Missouri, February 27, 1880.

BROWN, P. R., captain and assistant surgeon. To report in person to the president of the medical examining board for examination for promotion, and on completion of the examination, to the commanding general, Department of the East, for assignment to duty. S. O. 47, A. G. O., March 2, 1880.

FINLEY, J. A., captain and assistant surgeon. To report in person to the president of the medical examining board, in session in New York city, for examination for promotion, and, upon completion of the examination, to the commanding general, Department of the East, for assignment to duty. S. O. 47, C. S., A. G. O.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting will be held on Monday evening next, at eight o'clock, at the hall of the Medical Library Association. Reader, Dr. Garland. Subject, A Report of some Cases of Pleurisy in the Service of Professor Ellis, with remarks on the same.

FREDERICK C. SHATTUCK, M. D., Secretary.

SUFFOLK DISTRICT MEDICAL SOCIETY. — A meeting will be held at the hall, No. 19 Boylston Place, on Saturday evening, March 13th, at seven and a half o'clock. The following papers will be read. Dr. D. Hunt, Objections to the Proposed Law to regulate the Practice of Medicine. Disputant, Dr. E. W. Cushing. Dr. E. Cutter, The Salisbury Treatment of Consumption. Disputant, Dr. E. Cheney. All members of the Massachusetts Medical Society are cordially invited to be present and to take part in the discussion. Supper at nine o'clock. T. M. ROTCH, M. D., Secretary.

BOOKS AND PAMPHLETS RECEIVED. — Contributions to the Physiology and Pathology of the Nervous System. Part I. By Isaac Out, A. M., M. D.

The International Scientific Series. The Crayfish. By T. H. Huxley, F. R. S. With eighty-two illustrations. New York: D. Appleton & Co. Boston, 6 Hawley Street. 1880.

Transactions of the New Hampshire Medical Society. 1879.

Eleventh Annual Report of the Children's Hospital. Boston. John Wilson & Son. 1880.

Meddelelse om Skarlagensfeber af Aug. Koren, Korpsslæge. I, II, III. From the Norsk Mag. for Lægevidenskaben. 1879. Christiania, Norway.

Treatment of Diphtheria. By Ira E. Oatman, M. D., Sacramento.

Atlas of Histology. By E. Klein, M. D., F. R. S., and E. Noble Smith, L. R. C. P., M. R. C. S., Part X. Philadelphia: J. B. Lippincott & Co. London: Smith, Elder & Co. 1879. (For sale by A. Williams & Co.)

Paquin's Thermo-Cautery, with Wilson's Antithermic Shield, in Epithelioma of the Cervix Uteri. By H. P. C. Wilson, M. D., Baltimore, Md.

Boric Acid. A New Remedy in Eye Diseases. By Samuel Theobald, M. D., Surgeon to Baltimore Eye and Ear Dispensary, etc. (Reprint.)

Clinical Notes upon the Use of the Galvano-Cautery. By William A. Byrd, M. D., Quincy, Ill. (Reprint.)

Nitro-glycerine as a Remedy for Angina Pectoris. By William Munell, M. D., M. R. C. P., Lecturer on Practical Physiology at Westminster Hospital, etc. London. (Reprint.)

The Medical Annals: A Journal of the Medical Society of Albany. Vol. I. No. 1.

The Causes and Results of Pulmonary Hemorrhage, with Remarks on Treatment. By Reginald E. Thompson, M. D. Cantab., etc. With Illustrations. London: Smith, Elder & Co. 1879.

Monthly Bulletin of the North Carolina Board of Health. Wilmington, N. C. January, 1880. Thomas E. Wood, M. D., Secretary.

Norris on the Discovery of an Invisible or Third Corpuscular Element in the Blood. Abstract, with a Critical Note by Mrs. Ernest Hart. (Reprint from London Medical Record.)

Report on the Revision of the United States Pharmacopœia preliminary to the Convention of 1880. By Charles Rice, Chairman of the Committee. New York. 1880.

The Therapeutics of Gynecology and Obstetrics. Edited by William B. Atkinson, A. M., M. D. Philadelphia: D. G. Brinton & Co. 1880.

Excerpta from the Annual Report to the Board of Health for 1879. By Joseph Holt, M. D., Sanitary Inspector, New Orleans.

Pharmacology and Therapeutics; or, Medicine Past and Present. By T. Lauder Brunton, M. D., F. R. C. P., F. R. S. London: Macmillan & Co. 1880. (A. Williams & Co.)

Classical Writers. Edited by John Richard Green. Virgil. By H. Nettleship. New York: D. Appleton & Co. 1880.

Ceremonial Institutions, being Part IV. of the Principles of Sociology (the first portion of Vol. II.). By Herbert Spencer. New York: D. Appleton & Co. 1880.

Skin Diseases, including their Definition, Symptoms, etc. A Manual for Students and Practitioners. By Malcom Morris. With Illustrations. Philadelphia: Henry C. Lea. 1880.

Original Articles.

CASES OF INSANITY AND OF FANATICISM.¹

BY CHARLES F. FOLSOM, M. D.,

Lecturer on Hygiene and on Mental Diseases in Harvard University.

Mr. F. is the next to youngest child of five, four of whom are in good health. There is no known insanity in the family. The father is still living, of very intemperate habits; the mother died of cancer. Mr. F.'s general habits are good; he has used tobacco, but never to excess. He was always strong-willed and very conceited.

When fifteen years old he enlisted as drummer boy in the recent war, and served to its close; he had many hard marches, and was several times ill with dysentery. At the age of twenty-one he "experienced religion," having worked at "healing" in a Lynn shoe manufactory since the war, with the exception of a year passed with a brother in the town of Natick. In Lynn he became acquainted with his wife, employed there stitching shoes. He worked so hard to save money to get married that he broke down in 1871, and had to take a vacation, upon his return from which he was married, at the age of twenty-five, a year after having had an attack of diphtheria. In 1875, business being dull, he removed to Pocasset, the home of his wife, and took a small house, nearly a half mile from his nearest neighbor; Pocasset being a village of three settlements, about a mile and a half apart, containing in all about eighty houses, and from three hundred and fifty to four hundred inhabitants. He employed himself carrying the mail between the railroad station and the post-office, for which he was paid one hundred and fifty dollars a year, took care of the Methodist church, and raised a few crops on a small piece of land, keeping a horse, and also one cow, whose milk he sold when he had any to spare. In the summer of 1876 he was overworked by exposure to the sun in haying, felt weak, nauseated, with a feeling of oppression about his head, so that he had to give up work, and has not been able to wear a stiff hat or a tight one since that time. His family physician remembers having heard him complain of his head a year later. He is a rapid, fluent speaker, very bright, of not much education, thoroughly kind, humane, affectionate, and extremely fond of his family, especially the younger daughter, who was his constant companion.

February, 1878, in the church, one evening, he heard the Old Testament preached, and thought if it were all true, and men lived up to it, they would soon be in the poor-houses with their families. It made such an impression upon him that he had to go home, leaving a friend to put out the lamps and shut up the church, thinking that no one lived up to the religion which he professed to believe. On reaching home, he found a paper called the Golden Rule, and in it a sermon on renunciation by a popular preacher. He came to the conclusion that the only way to find out whether the Bible were true would be to live up to it, to follow the letter to its logical sequence, and see whether God would support a man in it, as "the Spirit of God leads a man in the opposite to the natural direction." He began to discuss religious doctrines incessantly,

and went about to those acquaintances with whom he had any differences and said he wished all to be forgotten, as he meant to lead a new life of devotion to the Word and Spirit of God. He "experienced religion" a second time at the Methodist camp meeting, — the first having been in Lynn years before. He spent much time poring over Josephus and the Bible.

He thought the Lord asked him to consecrate himself to his work, to the exclusion of every other duty, even to letting his family starve if necessary. He struggled with the question for several days, and then yielded, when he thought he was rewarded for his act of faith by the Lord's not requiring him to do it. Again the Lord asked him if he would renounce his family altogether, and never see them again, in order to go and preach the gospel. The question at first "staggered" him, as did the former on consecration, but finally he consented, and the Lord rewarded his faith by not requiring him to do it, as in the former case, and by giving him clearer light to see the meaning of the Bible. He said that he always talked with the Almighty as if he were a boy fourteen years old, and God always held him to his word.

In the summer of 1878 he had his "baptism by water" under the Adventist leaders, Wing and Brown, although he says he got his inspiration and communications directly from God. He had a great vision, beginning while he was asleep, although he is sure he did not remain so, for everything was very vivid and real, and he recollects getting out of bed to pray. A heavy black cloud settled down on him; he heard some voices plainly and others faintly, is not sure what they said. He was translated three fourths of a mile to the house of his mother-in-law, and saw a terrible whirlwind, with noise of hail and thunder, so that the adjacent house of his brother-in-law was leveled with the ground. He was very much frightened. The Adventists soon became so demonstrative that they were forbidden to hold their meetings in the church, and afterwards were prohibited from using the school-house for that purpose. On the departure of the Adventist leader from Pocasset, F. at once became the acknowledged head of the sect in that village. There arose a bitter quarrel, and F.'s brother-in-law forbade his wife having anything to do with F. or his family, which he considered to be a fulfillment of the vision just related; and his followers thought him chosen of the Lord because of the vision and its fulfillment.

In December, 1878, the Lord required him to give up relations with his wife. He wondered whether the suggestion were from the Lord or the devil. He and his wife argued the point, standing in their night-dress in their chamber. He finally consented, and then, as in the two cases before, of consecration and renunciation, he found the Lord did not require him to do more than show his faith.

In these communications from the Lord there was no act of the will, but they came beyond his power to bring them or prevent their coming. They were always accompanied with a peculiar, indescribable sensation, as if something was going from the ends of his fingers, a sinking sensation about the heart, and a feeling lasting about fifteen minutes which he could not explain, but it was not unconsciousness.

Nine weeks before the homicide he had another revelation that he should lead a life of celibacy. He and his wife both finally agreed to give up their relations for three weeks, to see whether the Lord really

¹ Read before the Boston Medical-Psychological Society, February 5, 1880, and also before the Boston Society for Medical Improvement.

meant that. At the end of that time, for a trivial reason, he concluded the Lord meant for them to abstain, which they did for the remaining six weeks of their living together. At a meeting one evening, about this time, he had an uncontrollable fit of crying, and wondered whether it was a sign that the Lord meant him to renounce his family and go away to preach. He became irritable and impatient with his children, whom he really loved very much.

Three weeks before the murder he had his second great vision, one afternoon on lying down for a nap. A cloud settled down over him; his head and chest seemed as if afire; a tornado swept by, and he heard the sound of thunder (which Dr. Denny thought might have been suggested by the striking of the clock). He saw himself standing in a room in his night dress, with a dim light from a candle. A voice said, "Jesus is here, Jesus is here." He says he is sure he was not asleep, but remarked that it was quarter past three when he awoke. He could not understand the Lord's meaning, and could not sleep any more than if he were of glass, being in great agony.

Ten days later, and also ten days before the homicide, his wife's sister was at F.'s house, when her husband, a violent-tempered sea-captain (not the same brother-in-law as the one already referred to), found her there against his orders. He had a gun with him, and threatened to shoot Mr. F. This made such an impression on him that he could not attend to his work, although he continued to carry the mail. There was an awful feeling as if God were actually in the house, and about to require some great sacrifice of him. For the next ten days he ate only bread and cracker very sparingly, and drank only water, sleeping very little, scarcely an hour at a time, breathing so heavily in his sleep that he could be heard distinctly in the next room.

All of this time, while nominally the leader of the Adventists, he considered himself far in advance of them all, as having direct relations with God, and being chosen to do a great work second only to that of Christ. He remained in the greatest agony to find out what the Lord meant by this vision, and in great fear from the threat of his brother-in-law to shoot him.

Four days before the murder, he told a young girl, sick with consumption, that he could restore her to health, if she would have faith in him; and the day before it he went to a sick Adventist and said that it had been revealed to him that he should get well.

Three days before the murder, he became convinced that the Lord meant him to go away and preach, but he did not know where. He had just money enough to go to Boston, and he told the postmaster that he meant to give up carrying the mail in a few days, — a great act of faith, for the one hundred and fifty dollars a year from it constituted then his only income.

The next day his wife read in an Adventist paper of the sacrifice of Abraham, and asked him if he could perform so great a sacrifice, if that was what the Lord meant to require. He was shocked, and thought it preposterous, and then felt it so absurd that he laughed outright. After having slept a little that night, he began soberly to think whether he could do so, and laughed aloud again, the idea seemed so absurd. However, he soon concluded that some sacrifice was necessary, but did not know whether the Lord meant to take him, his wife, or one of the children. He felt that the one to go was to be taken by sickness and die, as did his

first-born child, of diphtheria, some years before. He told his mother-in-law that if there was anything between her and God she had better make it square with Him, and give God the benefit of the doubt.

This brings us up to April 30th, the day before the homicide. His family physician had noticed undue excitement for the previous month, and that for a week F., instead of being loquacious as usual, had been taciturn and moody, even passing his friends without recognition. He had been living a life of intense religious excitement for six months, and had himself remarked an uncommon weariness and inability to work; indeed, he had said that he was getting prematurely old; and some former friends visiting him, several months previous, from Lynn, remarked that if he were not then insane he soon would be so.

During the day, a tramp had called for food, and upon being generously treated left F. an old case-knife, with a rough blade six and three eighths inches long, one inch wide, and tapering to a point, the handle being of wood, five and one eighth inches long, four inches round, and bound at the end with tin. That evening F. and his wife went to the Adventist meeting, and he spoke fluently. On the way home they saw lightning, which both remarked upon as being unusually red, and a black cloud was thought to cover the moon. F. was sure that was a sign from the Lord. They went to bed, and he awoke between one and two o'clock with the sensations which he usually felt in his revelations. He was shown that the Lord meant to test his faith by asking him, as he did Abraham, to kill his beloved child. His wife told him he was wrong then if never before in his life, and tried to dissuade him from it. He went to the room where he occasionally had worked at shoemaking, got the knife left by the tramp the day before, as specially ordained by God, in his mind, sharpened it, as he had seen pigs stuck clumsily and wanted his child killed at once, if at all, and then went back to his wife's chamber. She still tried to dissuade him, but he assured her that all God wanted was a test of his faith, and that, as on previous occasions, He would not require the deed to be done. She said, "Go, and God be with you," but neither then thought that the child was to be sacrificed, although F. was prepared to do it, if the Lord so required. "One moment of agony," he said, and "then everlasting peace."

On finding himself standing in his night-clothes, holding his head with his hands, in the room dimly lighted by a kerosene lamp in the chair, he recognized the position as being identical with that of his vision three weeks before, and knew he had found its interpretation. He raised his hand to the highest, kept it up a long time to give God plenty of time, brought it down and struck the bed. He then raised it again, and on bringing it down pierced the walls of the heart, when the child died almost instantly, moaning, and simply regaining consciousness a moment to say, "Oh! papa," — and not suffering much pain, as he prayed might be the case if the sacrifice should be required.

The elder sister, at first unconscious of the act, was then awakened and sent to her mother. She had only a vague recollection of the matter, and says, "Edie moaned dreadfully." F. lay quietly on the bed with the dead child, feeling a great sense of relief. Mrs. F. then went to the next room and said "Oh! Charles! how could you do it?" He answered, "I promised the Lord I would, but thought He would stay my hand." He had hoped and felt that there would be a

moment of agony in consenting to do it, and that then he would be the favorite servant of the Lord, and he and his child would go out and preach a new salvation. He had been baptized with water and of the Holy Spirit, and hoped for the baptism with fire.

He soon had another revelation that the child would rise before morning, and went quietly to sleep. After an hour of intense suffering on the part of himself and wife when they found the child did not rise, he had another revelation that she would do so on the third day. Up to this time none of the other Adventists had any idea that such a sacrifice had even been thought of. A neighboring fanatic, Mrs. H., was sent for at eight o'clock in the morning, and her husband came two hours later. They were at first shocked, but soon were filled with the delusion as to the resurrection. F. carried the mail unconcernedly that morning, and then gave it up, and asked Mr. H. to take his place, until a successor should be appointed. During the day, he sent to all the Adventists and to the leading people in the town, including the physician, selectman, and Methodist minister, to come to his house, as he had a special announcement of great importance, which they supposed to mean his going away to preach, especially as he said it would be his last meeting in Pocasset. None but Adventists appeared, the meeting being in the middle of the afternoon. There were present: Mr. and Mrs. F.; Mrs. D. and daughter; Mr. and Mrs. S. and daughter; Mr. and Mrs. W. and two sons; Mr. and Mrs. G.; Mr. and Mrs. H.; Mrs. S.; Miss C.; Miss W.; Mr. and Mrs. H. — or twenty out of the twenty-three Adventists.

F. spoke fluently of the lightning and the cloud over the moon on the previous evening, and of his many revelations and visions, and then showed them the dead child, to their horror. He finally convinced them all of her resurrection on the third day. When the meeting dispersed, Mr. W. told two carpenters working for him of the deed, but otherwise it was not mentioned until the evening, when Constable R. ascertained the fact of Miss D., whom he happened to visit. Mr. R. at once called on Selectman N., to tell him of the homicide, and was sent to Mr. H. to ascertain whether such were the fact. In the mean time, lightning again, Thursday evening, was interpreted by F. as another revelation from Heaven that he had done rightly.

The next morning, the constable went with a friend to guard F.'s house, and the selectman drove to a railroad station, several miles distant, to telegraph for the sheriff and medical examiner. On their return, Mr. and Mrs. F. appeared perfectly calm. Mr. F. told the story minutely, even stopping from time to time to have every word put down, but showed great emotion when speaking of the child's death. He told his family physician that he should kill the other child if the Lord required it, and his wife sat quietly by darning stockings, without any of the emotion shown by her husband, sure that whatever happened the resurrection on the third day would fully justify the deed.

On the way to the jail Mrs. F. sat in the ear quiet and calm; Mr. F. sang religious hymns, and tried to harangue the passengers about his great mission as an evangelist.

Mr. D., the greatest fanatic of the others, was not at the meeting, and on reaching home, late Thursday night, at once saw the nature of the homicide, and set to work to disabuse the rest of their delusions. Most of them were brought to their senses in a day or two,

but some remained deluded until the third day, when Mrs. F.'s mother went to the room where the child's body had been put to see whether it had arisen. Mrs. F. thought the child would rise and the prison doors be opened on the third day; but when that did not happen, she too was convinced that her husband had acted from mistaken faith, and had simply murdered a daughter to whom they were both devotedly attached.

F. alone held to his delusion. When the child did not rise on the third day he was not troubled in the least, as he said the word day was used in the scriptural sense, and he did not know its length.

Previous to the murder, as afterwards, he was sure that he was within a step of Jerusalem, of being where the apostles started; that he had in his hand the silver keys to the kingdom of God and that he should have the baptism of the Holy Spirit, — it might take a day to get it, or a thousand years. Daniel, Michael, Cyrus, and Christ were represented in him, and especially Jacob. The twenty-three hundred days mentioned in the book of Daniel when Michael shall stand up ended on the day of the murder, and he was Michael, who also was Jacob. He never before felt so happy and full of peace as after killing his child.

Soon after going to jail he had his third great vision, and "the third baptism, with fire" as a reward of his faith. He felt so cold that he could not get warm by piling on all the bed-clothes. It seemed to him as if he were in a "rush of water" and all attire inside throughout his body. He was dazed for several days, and since then his life has been filled with revelations and minor visions, one of them being that the prison doors would be opened May 21st, with great phenomena from the heavens, and that the kingdom of God would be preached by him with his risen daughter, who would appear in a cloud of light, etc.

F. and his wife both refused counsel, saying that they were in the Lord's hands, and only consented to have lawyers appointed for their defense when they found the court would require it. It should be said, too, in passing, that the Adventist papers mentioned the homicide as an insane act, due no more to one form of religion than another.

I saw Mr. F. three times before the sitting of the grand jury in October. He appeared a man of high sense of honor, with a very keen general appreciation of right and wrong, neat and particular in his dress, very scrupulous in his habits, and of tender feelings. His great love of his family, especially of the younger daughter, and his devotion to them were commonly observed and remarked upon. He could not refer to the killing of his child without completely breaking down, although if asked if he did aright he would at once break out into rapturous descriptions of his greatness, and boasted of his being so important a personage that his supernatural power was so felt by the other prisoners that they obeyed his slightest word, — a delusion based on the fact that when disturbing our conversation they kept quiet at his request.

The extravagance of his delusions, the very marked tremor of his hands and tongue, and the rapidity with which he rushed from one emotional state to another suggested to me general paralysis of the insane; but the failure to detect any, even slight, incoordination of any of the finer muscles, the want of permanent impairment of the memory, the absence of tabic symptoms or increased sexual impulse, the efforts to avoid being seen when strangers came in, convinced me that

such was not the disease in hand and, indeed, a general paralytic, so long ill, could not have written such letters as several which were shown to me. The three great visions, probably somewhere on the obscure border line between consciousness and unconsciousness, with symptoms somewhat like an *aura*, made me think, but only for a moment, that epilepsy might be an element in the case.

I could not find any evidence of disease of heart, lungs, liver, kidneys, or brain except the mental symptoms and indications of hyperæmia, at least partial, of the brain. I did not observe any marked pallor or congestion of the face, although the eyes were flushed. The brain was very tired, however, especially at my first visit, and Mr. F. could read only in snatches for the first five months of his confinement, without lying down to rest, and it was impossible for him to concentrate his attention. At times he was somewhat incoherent and illogical, and very easily lost the question put to him, but he was as a rule quite clear, and reasoned accurately. His pulse was, as I saw him, once quite slow, but commonly about 70, regular and weak. Generally he slept well enough, but lightly, after a couple of weeks of sleeplessness in the jail. Digestion not troublesome; no hallucinations of sight or hearing. He thought God worked through the other inmates of the prison to do things to help him, even when they were making profane or obscene remarks. He had apprehensions part of the time that other sacrifices might be necessary, but finally gave up that idea, although he was not quite sure even then whether some other revelation might be made to him to kill his wife or other child; and he would at any time do it if God so commanded. If he thought there was any danger of his killing the other daughter, in spite of his faith in God, he would want forty thousand bars and walls between them. Several times, indeed usually, I found a little uncertainty about him, and that he rarely repeated the same statement in precisely the same way as before.

He had no care for the future, knowing that he was in God's hands, and all would be right. If set free, he would have nowhere to go, and would at once come back to prison, — a curious inconsistency with his grand ideas, but probably due to his believing that he must await the Lord's time for the resurrection. He said he did not care for his wife's future, as she, too, was in God's hands.

Just before the homicide, he thought he was called to preach the life, and was ready to give up his wife and children forever for that purpose; but instead of that God guided him to murder and Barnstable Jail. Barnstable being in Cape Cod, and the cape being called sometimes the right arm of the State, his incarceration is spoken of in the Bible, where it is said that God shall hold his own in his right arm. The Bible says, "He shall stretch out his arm like a swimmer," which referred to the great swimmer Boyton, and showed that the present is the time for the fulfillment of Scripture. He had a large marble to toss in his cell, and when it broke he said it was the ball in a great waste mentioned in the Bible. In fact, nearly every trivial act or event in his prison life was referred to by him as being an illustration or verification of some passage of Scripture, and indicating that all the great predictions were being fulfilled. He knew he was right, and the rest of the world wrong in not believing him. In October, he came to the conclusion that he might not preach the gospel to audiences, but

still be the great light of the world. If he and his wife were hanged it would make no difference, for the great glory would come to pass in some way which would be shown.

In the October session of the grand jury he was indicted for murder in the first degree, and his wife was set free. He still maintained his composure, but on close questioning acknowledged that he hoped his wife would be sent to a more comfortable place than the jail. Since his so-called baptism by fire and the Holy Spirit, he had constantly said that he had attained everlasting life.

Between August 15, and October 13, 1879, there was an improvement in his physical condition, and the confused feeling about his head had disappeared, so that he could read and write without weariness. Between that time and January 28, 1880, there was still an improvement in his condition, and he had almost ceased to have direct communications with God or revelations. Although asserting his personal bodily immortality, and repeating that he and his wife stood alone on the top of Mount Zion, he expressed a doubt as to the resurrection of the child, and feared that his wife was going to have a hard time of it for the rest of her life. A new idea had come to him that he had killed the child under the influence of the devil, the devil acting under God, and that thereby he had overcome the devil; that his life represented the struggle in heaven between the archangel Michael and Satan. All murders illustrate this and bear on his case.

He was not allowed to plead at the trial, and the wife was objected to as a witness, on the ground of insanity. He seemed to me for the first time to show evidences of clearing up in his mind, and told me that he expected to be sent to an insane asylum.

Mr. F. was examined by Dr. J. H. Denny, Dr. C. A. Walker, and Dr. J. P. Brown for the government, and by myself for the defense. We were all agreed as to his insanity.

The testimony before the court was substantially as follows, in reply to questions by F.'s counsel, Hon. A. W. Boardman and C. Allen Taber, Esq.:—

Dr. Charles J. Wood, of Pocasset, was the first witness called. After testifying to his experience and his acquaintance with F., which had been intimate during the past seven years, he said that as far as he knew F. was an honest, humane, and truthful man, a good husband and a loving father; a man attentive to business, prudent, sober, and had no vices except the use of tobacco. After his conversion, however, two years ago, a change came over him; his conversation turned wholly on matters of religion; he seemed to consider business pursuits as of secondary consideration, and neglected his farm. The homicide having occurred the first of May, the doctor was asked as to anything peculiar he had observed in F.'s manner during the ten days immediately preceding. He said that on the fourth day before the homicide, at the railroad station, he appeared to be completely absorbed in thought, and entirely contrary to his usual custom took no part in conversation; there was a great change in his whole demeanor, and he did not appear like the Charles F. whom the witness had known. On cross-examination the witness testified that he observed nothing about the defendant that showed a lack of general intelligence and understanding. His conversation on matters of religion was coherent and logical according to his own way of thinking, and his quotations of Scripture were profuse, correct, and apt.

TESTIMONY OF THE JAILER.

Mr. Isaiah C. Innan, the jailer who had Mr. F. in charge since his arrest, said that when he first came under his care he was in a great deal of excitement, so much so that he was feverish. He remained in this excited condition of body and mind for some time. After that stage was gone through with he came to another. He said he had received signs in various ways. He said one night he heard a noise in his pillow. He

thought at first it was imagination, and he changed the position of the pillow, but the noise did not stop; he said also that at the same time he smelt a bad odor. This he said indicated the presence of bad spirits, and he pointed out scriptural proof of this. On another time the wind rattled a window on the corner of the jail building. This, he said, was a sign representing that he was a corner-stone. He continually referred to other signs he had seen and heard signifying his peculiar calling. His appetite has been good, and, as a general thing, he has slept soundly. On cross-examination he said there was no want of general intelligence in Mr. F.; he showed no deficiency of memory, and quoted Scripture with great fullness and accuracy. He understood perfectly the nature of the various legal papers that had been served upon him in the case.

TESTIMONY OF MRS. S.

Mrs. H. S., of Pocasset, Mrs. F.'s mother, was next called. She testified that F. was sober, industrious, humane, a good husband, and a kind and indulgent father. After his conversion he was not so avaricious for worldly gain as he was before. He felt that his first duty was to God. He was constant in attendance upon religious meetings, and was always ready to give his testimony for Christ. A marked change came over him during the ten days previous to the homicide. She detailed the circumstances of the visit by Captain H., F.'s brother-in-law, who threatened to shoot F. for leading his sister into the Advent faith. F. appeared to have been very much frightened, and was greatly depressed, lost his appetite, and was unable to sleep. This was during the period of the ten days referred to. He had a vision during this time, and heard the noise of a rushing wind and of thunder. He spoke of three baptisms, the baptism of water, of the Spirit, and of fire, and said during the week preceding the homicide that he had just passed through the second. He said he felt the presence of God in the house, and that he was filled with an awe that was almost fearful. He was glad to have people come to the house, as it relieved him of the pressure upon him. On cross-examination the witness testified that about twenty people attended the meetings. She did not know as he believed everything F. did, for she had not gone as far as he had. She believed in baptism by water and of the Spirit; she could not say about the baptism by fire, for she had not experienced it.

TESTIMONY OF DR. FOLSON.

Dr. Charles F. Folson, of Boston, was called. He testified that he first saw F. in August, and since then had seen him at various times, spending at each interview from half an hour to three hours with him. He told him of three visions which he had had. He said he considers himself at the present time as representing the archangel Michael, and that the struggle between himself and Satan represented the struggle between Michael and Satan in heaven. He thinks that he is in a position that is occupied by nobody except Christ and St. Paul. He feels justified in what he has done, and says that the Lord will show to the world in due time that such is the fact. I should say to-day that he is decidedly of an unsound mind.

Q. I will ask you if his mind is capable of comprehending fully the charge in the indictment against him?

A. Not fully, but within certain limits. He is able to understand the form and technicality of the proceedings, but I do not think he is capable of forming a reasonable judgment upon their importance or upon the result.

I think he would be of no aid to counsel defending him, in the challenging of jurors, the examination of witnesses, or in summing them, or in any way whatever. I should say the form of his insanity is delusional mania. And in this particular case the special form of it is in regard to religious matters. I should not want to say at the present stage of the case how far the disease had extended, whether it was simply trouble with the circulation and impaired nutrition, or whether it had gone further than that. I think his insanity is due to five causes, operating together. I will not say that either one, or either two, or possibly either three, would alone produce the disease, but I think that with the five operating together the chances are more in favor of mental disease resulting than not. Giving them in the order of importance which I attach to them myself, I should say, in the first place, hereditary tendency, which I consider in this case a very strong one. In the second place, religious excitement, which in the so-called emotional causes of insanity occupies the second place in point of frequency. In the third place, a mild sun-stroke which he had three years ago last summer, and from which, as I understand it, he has never entirely recovered. Fourth, I should say the fact of his having led a life of great excitement from the time when he was fifteen years old, when he enlisted as a drummer boy in the army, to the time of his going to Pocasset, four or five years ago, and of the change in coming

into a little village of three or four hundred inhabitants, where his mind was deprived of the stimulus to which it was accustomed and thrown upon itself. The fifth cause I should place in his physical condition. About eight years ago he broke down in health, and had to take a vacation, and about a year from that time he had an attack of diphtheria. These facts show that his power of resistance is not what a man would naturally have, and I don't think he has ever recovered the same physical condition he had before. In addition to this an important factor is the very serious fright he had nine days before the first of May. [The doctor referred in this to the threat F.'s brother-in-law made to shoot him.] During my examinations of him I noticed an extraordinary change from deep depression to very great exaltation, which I never saw in a sane man, and should not expect to. He would be much depressed and troubled, showing very great grief, and five minutes afterward amused, and speak in a jocular, pleasant way. Generally speaking, however, during the first three visits which I made from August 15th to October 13th, his condition was pretty uniformly one of very great exaltation,—so very great that I suspected a graver form of the disease than I at present think exists.

Q. Is his grief ever accompanied by any remorse? A. No, sir.

Q. Any sense of guilt? A. No, sir.

Q. Has he ever manifested or does he feel, in your judgment, any consciousness of having done wrong? A. No, sir, not the slightest. On the contrary, he thinks he has done as the Lord communicated to him directly, as He communicated to St. Paul and Christ.

Q. Would you say, doctor, that his delusion controls his will, or does he? A. I think, sir, that is just the distinguishing point between insanity and fanaticism. His delusion has got the control of him, whereas a fanatic, although inordinately devoted to one idea, still retains his judgment and power of self-control so far as to obey the laws of society. As far as his general intelligence is concerned I should not suppose that it was seriously affected. His delusion has got the complete mastery over him, to the exclusion of everything else, and he would not act in any way contrary to his delusions. So, although his general intelligence may be as good as it ever was, it is of little value. He could not be worse off, as regards ability to control himself or give a reasonable judgment about the homicide.

DR. DENNY'S TESTIMONY.

Dr. James H. Denny, of Boston, was the next expert called. He testified: I have examined Mr. F. with reference to the question of his intelligence and with reference to his delusion. I have formed the opinion that he is a man of good intelligence upon general subjects; that upon the subject of religion as applied to himself his mind is unsound in many particulars. I noticed that he was restless in his demeanor, beating the floor with his feet, and he would frequently smile without any apparent cause. There was evidence of overplus of blood revealed by the ophthalmoscope, and his temperature was abnormally high. There is a marked tenderness about the head on the lines of the sutures. I do not lay any stress on these evidences other than as corroboratory of other indications of hyperemia of the brain, such as might naturally follow such cerebral congestion as results from exhaustion and sun-heat effects testified to, and the state of active delusion which has been manifested in connection with intense headaches. At the present he is laboring under delusional insanity of a religious type. He would not understand the indictment as applied to himself, because his delusions impair his judgment. I have no doubt that he is not in a proper condition to prepare for the defense.

To the attorney-general. The specific delusions which I have observed in him are as follows: He supposes that he is the Spirit of Truth, the third person of the Trinity in his system of theology; that he himself will never die; that he is immortal, so far as this life is concerned; that when he is taken away from this world it will be in some manner different than by death; that he is the second Adam; that he represents in himself, in some way, the second coming of the Messiah; that he is one of the greater prophets, like Jeremiah; that he himself is the "elder brother" spoken of in the Scriptures. He believes that various passages of Scripture have been written with direct reference to himself and family, and not to others; that the world has been saved through him. In all of these delusions he has great system, and is extremely candid. He has told me that he has endeavored to prove by every means possible in his power the truth of what was presented to him by the Spirit; that he required as the apostles did, and received as the apostles did, supernatural evidence of what he believed with reference to himself, and that when he received supernatural evidence he used every method possible to determine himself, as a

thinking man, that it was supernatural and given by the Spirit to him. He tested himself with reference to the odor that he smelt, which he supposed was frankincense, in the pillow that was spoken of by the jailer. He tested himself with reference to the various sensations which he felt, the baptism of fire that he speaks of,—a sensation which came naturally from the congestion of his brain and over-excitement of his nervous system.

To the court. I have satisfied myself that these delusions were not simulated, and I feel perfectly sure of it.

To Mr. Boardman. I have never found in him any consciousness of wrong-doing, but, on the contrary, the most exalted sense of the right of his position, and his exaltation shows the course of his mind during the past two years. He at first felt he was called as an evangelist; then as one of the greater prophets; and then, in a still greater stage of exaltation, that he represents the Spirit of Truth, the third person of the Trinity; and, finally, he has accomplished the salvation of the world. There has been a steady progress so far in the exaltation of his religious ideas.

Dr. Folsom was recalled, and testified that F.'s insanity is not simulated. A man cannot feign this form of insanity so as to deceive a person who is familiar with it.

TESTIMONY OF DR. BROWN.

Dr. John P. Brown, of the Taunton Insane Asylum, in his direct testimony corroborated the other experts. On cross-examination he said: The leading delusion which Freeman manifested was that he was the promulgator of a new dispensation through the death of the child; that God had used him as an instrument in sacrificing his child, in bringing about a new dispensation for the salvation of the world. He stated to me at one visit that Christ's atonement did not include the salvation of children, and the sacrifice of his child was necessary in order to secure the salvation of children. That was the main delusion, but he changed the form of it several times. Once he said that he was the second Christ and God in man, and that he was the third person of the Trinity. He said that God had recently given him the power of discerning the spirit of evil in man; that if a person approached his presence, before he got near him he could tell by this power, which was imparted to him by God, whether the man was possessed of a good spirit or of a bad spirit. He said it had been illustrated to him in a great many instances, and he made a comparison this way. He said, "It seems to me as though a certain substance passes from the individual and into me. It oftentimes seems as large as my hand, and sometimes it is of a dark color." He would first have a mental impression and then a feeling in his chest. God asked him if he would be willing to give up and sacrifice all his property and family and everything on earth, whether he would be willing to have them swept away by God. He said when he had that mental impression he had a feeling at the same time of depression, a sinking feeling at the stomach. Last evening he told me distinctly for the first time that since my last visit it had been made known to him that his body would be immortal, that he would live as he is now in this body eternally. I have not had the slightest idea that he was simulating, although I have borne it in my mind, of course, at each interview.

THE DISPOSITION OF THE CASE.

Attorney-General Marston then addressed the court, and said that he was entirely content, representing the commonwealth, to assume that the evidence given by the experts had come from proper sources, upon proper examination, and that it disclosed as well as could be disclosed to the mind of the court what the condition of the prisoner was. Judge Morton said he felt bound to say that the testimony made it entirely satisfactory to his mind that the prisoner was not in a condition in which he could intelligently and prudently plead to the indictment. After explaining briefly the law and his interpretation of it as not giving him power, sitting during the vacation, to order a commitment to an insane asylum, he remanded the prisoner into the custody of the sheriff till the regular session of the court for Barnstable County, which would be about the first of May. He suggested, however, that the governor had power to commit. The court then adjourned.

Mr. F. at the close of the hearing shook hands with quite a number of his friends in the court room, and was then conducted back to the jail. He expressed himself as being satisfied with the result of the hearing, and will be glad to change his present quarters for some more comfortable if it is God's will. He was very careful, however, not to acknowledge by the slightest concession that he considered himself insane in the least, but if he was to go to an asylum he rather preferred Danvers, as being near his early home. "I am not insane because they say so," he said, "and I would stay here for years rather than

do anything to admit in any way that I had done anything wrong or that I am insane. If I am convicted of insanity the Bible must be shut up." "It is time now for the Spirit of Truth," he says, "the third part of the Trinity. Up to this time Father and Son only have been known. I am the Spirit of Truth." "I represent Christ in all his parts, prophet, priest, and king." "It has been prophesied that all shall be gathered into one; that it is me." "I have a dual nature; both Christ and man is represented in me, the son of man on earth." "All good is represented by one person, and I am that person." "I am the result of Christ's teachings; Christ's teachings are perfected in me." "My wife and I are the first two persons who have ever stepped into the kingdom of God; the Bible is of no more use for us; we have fulfilled it; we are saved, and cannot be lost. I feel sure that our names will be honored above any other name except Jesus." "We are the door, and everybody must enter through us." Speaking with reference to Dr. Folsom's testimony, in which allusion was made to F.'s belief that he was the archangel Michael, "Has the doctor ever seen him?" he asked; "does he know how he looks?" And then he said, "I am the archangel Michael; now let Dr. Folsom prove that I am not."

As already remarked, I thought I saw at the time of the trial evidence of some shaking in the firmness of the delusions, and was inclined to give a more favorable prognosis than I had formerly expressed: an opinion which I should say was not shared by the other physicians called upon to testify.

Three days after the trial, before leaving the jail for the insane asylum, he destroyed all his writings, hymn-book, etc., except his Bible, which he said he would willingly give up. He said to me, before reaching the hospital, that he should never say anything more about his faith unless questioned. When interrogated by old friends whom he met in the court room, he expressed great annoyance, and was not willing to answer any of their questions. I overheard him say that he meant to get cured in the asylum, if he had delusions, as the doctors all thought he had. In the next breath, however, he insisted that he had done right to kill the child. A little while before, he had said that the political stealing of the seal of state in Maine was a representation of the loss of the seventh seal of the Bible.

The delusions of Mr. F. and his act are, of course, conclusive of insanity; to my mind, the character of the homicide alone is just as conclusive, as much so as if the man had jumped from the top of a church, expecting the Lord to arrest his fall. So far as his homicidal act is concerned he belongs to that large class of the insane who are described as reasoning well from false premises. As Dr. Ray says of them, their insanity consists "in being unable to discern the essential identity of nature between a particular crime and all other crimes, whereby they are led to approve what in general terms they have already condemned." No amount of evidence is of any value to Mr. F. on this point.

Mrs. F. is also thirty-three years old, a few months younger than her husband. Her mother is of a family in which there have been several cases of insanity, and she now has a sister in the insane hospital at Worcester, whose son has also been insane. She has three sisters and two half-sisters, all well. Mrs. F. had, when eighteen years old, some convulsions attended with sudden loss of consciousness, which seemed from her description to resemble epilepsy. No physician had observed them. She sold her wedding presents and gave the money to a hospital for the sick (Consumptives' Home) late in 1878. Like the most deluded of the other Adventists, she came to her reason as soon as it was shown that her daughter did not rise

on the third day, and she remained so for a month, suffering most intense mental anguish all of that time. Only Christ, she thinks, has suffered as much. But constant brooding over these matters, being shut up in jail without occupation except from her thoughts, and, worst of all, often receiving from her husband notes concerning his insane delusions, she finally was "baptized with the Holy Spirit," in a flood of light, and saw that the child would rise in three "prophetic days," that is, days of unknown length. I copied down many of her delusions, but they were simply the same as her husband's, of which he kept her constantly informed. Mrs. F.'s mother essentially followed her daughter in some of her delusions, chiefly as to the resurrection; and after Mrs. F.'s release from jail, last October, a very few of the most fanatical formed a circle of believers around her on her return to Pocasset.

Mrs. F. really did little more than accept fully the delusions of her husband, after her month of feeling that the act was one of mistaken faith in God. After her release in October, she thought God had commanded her to go barefoot and naked, like Isaiah, to be a sign to the people, and did almost no act, no matter how trivial, until she had a sign from the Lord. After her husband was sent to the insane asylum, she altered her tone somewhat, expressing a desire to get away from the old associations, wishing to get employment to occupy her mind and make a living, saying that she needed rest, and hoping to have her other child with her. Public sentiment is now so strong against her in Pocasset that she cannot go back there.

Of course, these two are as clear cases of insanity as one could well see. I do not know of any form of human suffering more intense than delusional insanity, partial intellectual mania of this form, where persons are borne on by virtue of their delusions to commit acts from which they naturally shrink with the greatest horror. I certainly never saw two human beings who had a fuller right to the deepest sympathy of their fellow-men than these two insane persons.

So far as the other eighteen Adventists who shared the delusion of the immortality and bodily resurrection of the murdered child are concerned, little is to be said. With the exception of three, who are ill balanced, they belong to the sensible grammar-school-taught, neat, industrious Americans of the rural districts of New England. Their delusion, in the midst of the realities of the practical life of our day, is more like the witchcraft delusion than any other which comes to my mind, and opens a field for most interesting philosophical inquiry too wide to be entered upon here. It would be difficult to find a more curious illustration of the fallibility of the human mind, especially among people who now are as totally at a loss as others to explain their singular mental freak. The most fanatical of the Adventist community, next to F., has swung to the opposite extreme, and would have the doctrinal churches and usual Bible teaching abolished.

Of course, the insanity of F. and his wife cannot be a matter of dispute among competent persons. Fifteen of their associates were as clearly simply fanatics. If I were required to positively place the other three, with my present knowledge, I should be in great doubt on which side of the line between fanaticism and insanity to put them; for insanity, as compared with fanaticism, or even with sanity, is often merely a question of degree, depending upon the extent to which the power of rational self-control has been lost.

THE TREATMENT OF IRREDUCIBLE HERNIA.¹

BY J. COLLINS WARREN, M. D.

THE object of this communication is to call attention to a mode of practice which, although not new, has received but little attention from surgical writers since it was brought to notice, about twenty-five years ago, by Maisonneuve, whose chief weapon was the rubber bandage which has lately come so much into use in this country. We find, indeed, fragmentary allusions to curative treatment of this disease in early writers, chiefly by rest in the recumbent posture. Arnaud² describes a case, and Sir Astley Cooper alludes to the possibility of reducing large and old herniæ by appropriate diet and purgatives. It would be possible, without doubt, to trace these methods back to a much earlier period. Before calling your attention to them, I wish to refer briefly to some of the causes of the permanent irreducibility of herniæ. These may be found chiefly in the secondary changes which take place with the lapse of time in the character of the sac or of its contents. When the sac is first formed the neck, like the mouth of a bag, is thrown into folds; so long as the sac can be returned into the abdomen these unfold themselves and disappear, but after the sac has remained unreduced for a considerable length of time the sulci between the contiguous folds become obliterated by bands of adhesions. A permanent ring or neck is thus formed. The surrounding subperitoneal tissue becomes in the mean time more vascular and considerably hypertrophied; strong bands of tissue form around the neck, which in old cases sometimes assumes an almost cartilaginous hardness. This tissue is at times quite contractile, so that it has been thought by some to be a cause of strangulation. When the contents of such a sac remain "reduced" for some time the ring may contract so vigorously as to shut off all communication with the abdomen, and we then have what is called the uninhabited sac. The whole wall may by this time have become exceedingly thickened, not unlike an old hæmatocele, and, as in the latter disease, it may inflame and suppurate. In addition to this hypertrophy there are many changes brought about by the gradual development of the hernia. The ring may be forced from its bed by some unusual violence, which brings down a fresh installment of sac and contents,³ forming an hour-glass-like contraction, and this may be repeated several times, giving the sac a varicose appearance. The mass thus thrust down may force its way completely in front of the old hernial tumor, which will thus be concealed behind it. Like the old thickened hæmatocele alluded to, we may have thick bands formed from old adhesions extending across the sac in different directions. It does not necessarily follow that this state of things when once produced will remain so permanently, for with increasing size the ring may be dilated, the bands torn from their insertion and absolved, and the sac wall much thinned by distention. It will thus be seen that in a large hernia, rapidly increasing in size, conditions are constantly changing, and it may have become more susceptible of reduction than it was in an earlier stage of development.

If we turn now to the contents of the hernia we

¹ Read before the Boston Society for Medical Improvement, March 8, 1889.

² Arnaud, *Traité des Hernies*, tome ii, page 135.

³ Schmidt in Von Pitha and Billroth's *Surgery*, page 28.

shall find that the chief obstacle to reduction is the adhesions formed by them with the walls of the sac. These are most likely to occur when the hernia is omental; according to Gosselin¹ the adhesion of the intestine to the omentum or sac is exceedingly rare, such as we find when an operation for strangulated hernia is performed, being soft and due to recent peritonitis. This is explained by the different character of the two structures, the immobility of the omentum in its new bed favoring adhesion. The intestine, however, may become adherent either to the sac or to the omentum.

The omentum after long residence in a hernial sac undergoes considerable transformation of structure. It soon loses its membranous character; the adipose tissue may become greatly hypertrophied, grouping itself in large, nodulated masses; the veins become greatly dilated, and the connective tissue thickened and indurated. The folds, lying in contact with one another, contract adhesion, and the mass may finally be converted into a long, tough cord, or rolled up into a ball attached to a long pedicle, forming a sort of ball valve, preventing any fluid secreted from entering the abdominal cavity.² When there are both intestine and omentum in the sac the hernia is usually of large size, and although symptoms of strangulation may occasionally appear it is extremely rare that any operation becomes necessary, as genuine strangulation does not take place. These symptoms are caused by a hernial peritonitis, which spreads through the ring, but which yields to rest and appropriate medical treatment. Not only is the ring large, but the sac, being already full, does not admit of considerable increase of contents. The hypertrophy which the omentum undergoes may be sufficient to prevent its reduction even if there be no adhesions. A great obstacle to the reduction of large hernie has been found in the diminished size of the abdominal cavity, so that, although the viscera can be returned, it is impossible to retain them there owing to the distress and colic which their presence causes. This has erroneously been supposed to be insuperable. The size sometimes becomes enormous. The most notable example is that of Gibbon, the historian, described by Cooper.³ It was a left scrotal hernia, of thirty years' standing, and reached to his knees. The lower portion was, however, a hydrocele containing several quarts. He succumbed to a peritonitis following an evacuation of six quarts by tapping, and at the autopsy it was found that the abdominal cavity was nearly emptied of movable viscera, and that the pylorus lay at the opening of the sac, which was large enough to admit a hand.

Attempts to remedy this disease were first suggested by the observation that during prolonged illnesses large irreducible hernia returned spontaneously into the abdominal cavity. Cooper evidently proposed to imitate this by extraordinary fasting, diaphoretics, and cathartics, but he could never persuade any one to undergo this treatment.

Maisonneuve⁴ appears to have been the first who attempted a systematic mode of treatment. The main feature of this method consisted in the use of elastic pressure, by means of the rubber bandage

which has since become so fashionable in this country. It was about twenty-five years ago that he first treated irreducible hernie in this way.

When the tumor was large and could be gathered up at its base into a pedicle, the bandage alone was used. A few turns were taken tightly over the pedicle to prevent an escape of the tumor, which was then carefully covered in by circular and oblique turns. Having used it with great success in a large number of irreducible hernie, Maisonneuve subsequently applied it to strangulated hernie, which were thus reduced in the space of a few minutes. When the tumor could not be pediculated, direct compression was applied by an instrument which consisted of two pads, one to be placed upon the back, the other over the tumor, the two being connected by horizontal shanks, the ends of which were bound together by the elastic bandage. Further pressure could be produced by a screw attachment of the pad.

Gosselin describes a case from Arnaud of large scrotal hernia, which was treated by rest for thirty days, baths, purgatives, mercurial treatment, three venesections, and a restricted diet, with the local application of *emplâtre de Vigo*. Lannelongue⁵ conceived the idea of pressing or pulling back, the hernial mass through the abdominal walls by means of a bag of shot weighing two pounds placed above the neck of the tumor. It was supposed also to paralyze the action of the abdominal muscles.

Among English writers I find little said upon this subject. Agnew⁶ says, "When there is reason to believe that the obstacle to reduction is of recent origin, as the formation of an inflammatory adhesion either from violence or from neglect to wear a truss, it will be proper to make an effort at restoration. With this end in view, the patient must be confined to bed, with his shoulders elevated and the limbs drawn up. Pressure over the tumor to an extent not incompatible with the comfort of the person should be made by a bag containing shot,—a kind of compress which adjusts itself neatly to the form of surface upon which it is placed. The diet should be restricted; absorbents, like the iodide of potash and the bichloride of mercury, administered; and once in six or eight days an active purge given, both with a view to aid in the absorption of the incarcerating bands of lymph which detain the contents of the sac in their unnatural location, and to detach and separate the same by exciting peristaltic movements in the protruded bowel. If such a course be maintained for three or four weeks the surgeon will occasionally have the satisfaction of finding the hernia restored to the abdomen. Except, however, when the irreducibility depends upon a cause like the one above mentioned, the probabilities of restoration in the form of hernia under consideration are so slight that it will be useless to subject the patient to any such course of treatment."

Gross⁷ advises, should the attempt be made, absolute rest in the recumbent posture, low diet, venesection, purgatives, mercurials, and sorbent applications. "Occasionally steady, systematic compression answers a good purpose; maintained either with adhesive strips, as in the treatment of subacute orchitis, or by means of a truss with a hollow pad, progressively lined with layers of leather, or furnished with

⁷ Gross's System of Surgery, vol. ii. p. 679.

a gum-elastic air cushion." He adds, "In the few cases in which I have employed it I have found it extremely difficult to secure the hearty coöperation of the patient beyond six or eight weeks, and I am satisfied that few persons will be found willing to submit to it even that long."

The method which I have employed with success in several cases differs from those described above in the employment of rest in the *inverted position*; that is, the foot of the bed should be so raised that the neck of the hernial sac should be at a higher level than any portion of the abdominal cavity, and that not only all intra-abdominal pressure should thus be removed, but that gravity should aid in returning the hernial mass into the abdomen. No special medical treatment was found necessary.

When the descent of the hernia is comparatively recent and consists of intestine only, no additional mechanical appliance is needed.

The two following cases, illustrating this point, are taken from the record book at the Hospital:—

J. C., thirty years old, entered with an inguinal hernia of four months' standing. Whether irreducible during this period is not stated. A prolonged attempt at reduction by taxis under ether was unsuccessful. The patient was placed in bed in the inverted position, and at the end of eight days the hernia had reduced itself.

J. W., aged forty years, had a left inguinal hernia of twelve years' standing, which for a few days past had become irreducible, and at time of entrance to hospital was slightly painful to touch. It was about the size of the fist and very hard. Taxis under ether was unsuccessful. After he had remained in bed for six days in the inverted position the hernia reduced itself, without further assistance.

When the hernia is of the large and mixed variety various mechanical appliances must be brought into requisition, and the active and intelligent coöperation of the patient is indispensable, as the following case will show:—

H. R., about forty-five years of age, has suffered from an irreducible hernia for twenty-five years. When small it was accompanied by a varicocele, which was operated upon by a French surgeon. It has steadily increased in size, in spite of support from suspensory bandages of varied device, and of late years the increase has been very rapid, until, at the time treatment began, it measured seventeen inches round the pedicle and extended half-way to the knees. It was an entero-epiplocele. The skin of the scrotum was tense and shining, the penis had disappeared from view, and the groins and thighs were in an irritated eczematous condition. The discomfort of the patient, was greatly increased by excessive corpulency, which, despite a very active life, had recently developed itself. A portion of the hernia could be reduced, but an attempt to replace more than a limited amount was followed by nausea and abdominal pain. A strong iron bedstead, to which was fitted a wooden bottom, for extra support, having been selected, the feet were raised on wooden blocks about eight inches in height. A large, wedge-shaped hair cushion, made like a mattress, was employed to elevate still further the pelvis when desirable. Owing to the patient's great weight, it was found that his head slipped down between the iron bars of the head of the bed during the night. This was obviated by a device ingeniously

contrived by himself,—a wooden yoke that braced against the shoulders, allowing the head to be free in a space hollowed out for the purpose. The scrotum was supported in a vertical position by a hard rubber splint specially prepared. No pressure was applied for three weeks, during which the inverted position was carefully preserved, except at meal-times, when a semi-recumbent posture was allowed. The diet was that of a person in ordinary health; the bowels were regulated by laxatives. The activity of the circulation was maintained by massage, and the hernial tumor was gently manipulated to facilitate the absorption of inflammatory tissue. By this time it was noticed that rugæ were beginning to form on the scrotum. Pressure was now applied to the fundus by a small sand bag weighing four pounds, and this weight was rapidly increased, with favorable result, a marked diminution in the size of the hernia soon showing itself. A great variety of methods of exerting pressure were tried. The use of compressed sponges was on the whole not satisfactory, owing to the difficulty of confining them effectively in this region of the body. The rubber bandage, used as Maisonneuve recommends, produced a most formidable pressure, but its effectiveness was impaired by the fact that the pedicle made by it was separated nearly *four inches* from the inguinal ring by adipose tissue. Moreover, the constriction necessary in the first few turns to enable the bandage to retain its hold was so great that I could never induce myself to keep it on longer than a couple of hours at a time. These first turns of the bandage curl up into a rope, and strangulate so powerfully that prolonged application would be dangerous. This difficulty may be overcome by making a pedicle with strips of adhesive plaster first, thus forming a collar two or three inches wide, over which the bandage may be applied. The bandage was used more efficiently and comfortably, in connection with pads and compresses, applied in figure-of-eight turns round the groins and over the scrotum. By means of a hoisting apparatus, similar to that described in Hamilton's work on fracture, the hips were still further elevated at intervals during the day. At the end of the eighth week about two thirds of the mass had been reduced, but there was still two large hands full of omentum remaining. To attack this a rubber water bag had been prepared (Figure A); externally inelastic, but

FIG. A.

FIG. B.

containing an elastic lining inclosing a space to which water or air could be admitted by a tube (B). To this was sewed a stout T bandage to secure it to the scrotum, and when once buckled in place it was pressed firmly down upon the pillars of the ring by thick wooden pads, which were held by turns of a rubber bandage. By means of the tube the pressure of a column of water of any desired height could now be

applied, but it was found that inflation by the lungs was sufficient at first. A few hours later the air was replaced by water pumped in with a Davidson syringe. This pressure was maintained fifteen hours, at the end of which time the hernia was completely reduced.¹ An examination the next day showed the ring large enough to admit four fingers at once. The patient is now wearing a truss the pad of which is four inches in depth, and is actively employed in the duties of his profession.

I have used this bag in a second case since, without success thus far; but there are complications, such as an incision at one time, laying open the sac by mistake for a hydrocele, which have produced an unusual amount of adhesion. The case is still under treatment.

The bag seems to possess great advantages over the bandage, as the pediculated form, so desirable, is preserved and strangulation avoided. The pressure is soft and evenly applied in all directions, and capable of being exerted with great force.

In cases where these methods fail I should recommend a prolonged trial with taxis under ether, preceded by manipulations intended to loosen adhesions in the ring which can be accomplished by the finger introduced beneath the invaginated scrotum.

I have found in the hospital records several cases treated successfully by Dr. Cabot in former years with the rubber bandage, with rubber air cushion, or with pigs' bladders.

RECENT PROGRESS IN THE THEORY AND PRACTICE OF MEDICINE.

BY A. L. MASON, M. D.

ANIMAL VACCINATION IN ENGLAND.

IN England vaccination is compulsory, but heretofore the public authorities have confined themselves to the use of human lymph. The alleged deterioration of the supply from this source, and the agitation of the anti-vaccinators, based chiefly on the danger of inoculating syphilis, led Dr. Cameron, M. P., to prepare a bill, to be presented to Parliament, which aims at the official introduction of bovine lymph. The conservative character of the Government Board may render this innovation difficult of accomplishment.

The consideration of Dr. Cameron's bill occupied several conferences of the Parliamentary Bills Committee of the British Medical Association, at the rooms of the Medical Society of London. Mr. Ernest Hart, chairman of the committee, presided, and the final meeting took place December 31st. Full reports of these meetings, of which the following is an abstract, are contained in the *British Medical Journal* and *The Lancet*, January 3d and 10th. The chairman, feeling that the time had come when a large census of medical opinion should be taken as to the propriety of introducing and encouraging the use of vaccine lymph, direct from the calf, suggested to the committee to invite a public expression of the views of those who were best qualified to judge of this important subject; and the result was to elicit numerous and weighty utterances from the most representative men. With but one or two minor exceptions, the speakers at the conference expressed themselves as favorable to the use of

animal lymph, almost the only objection urged to it being its alleged expense of application, the fallacy of which the chairman of the Parliamentary Bills Committee has already exposed in his report. Even the officials representing the Local Government Board had no objection to bovine vaccination; and it is certain, from what Dr. Ballard said, that the Local Government Board views it with no disfavor. It was not desired to supersede arm-to-arm vaccination, but only to provide for the renewal of stocks when a vaccinator finds them from any cause giving less efficient results, and to furnish the material where-with to vaccinate children whose parents have conscientious objections to humanized lymph. The favorable opinions of calf lymph expressed by men like Sir Thomas Watson, Dr. Warlomont, Mr. Ceely, Dr. Braidwood, Dr. Alfred Carpenter, Dr. Bristowe, Dr. E. T. Wilson, Mr. Greene, Dr. Drysdale, Dr. Wyld, and the other gentlemen who addressed the conference cannot but have their effect in pressing forward a reform which the Local Government Board seems to be now disposed reluctantly to take up.

In conclusion the chairman said, "The committee will have the duty imposed upon them of drawing from the report of all that has been said and done at this meeting the conclusions arrived at, and they will also be required to find what those conclusions are and to act upon them. I shall now make one or two observations as to what has occurred. I cannot but think that the whole course of the discussion has been very markedly to strengthen the conclusion that, in some form or other, it will be the duty of the government to arrive at a solution of the question, in what way and to what extent our system of vaccination may be strengthened by introducing animal vaccination as a source of improvement to the vaccine lymph. I myself am gratified, and I imagine the majority of this meeting are gratified, with the observations of Dr. Ballard and Dr. Stevens. We have heard the last observations of those gentlemen; and I am satisfied with them, because they appear to me to show that, at the conclusion of this conference, these gentlemen—who are not after all merely the official representatives of the government, but also men of particular, unique, and life-long experience in the matter—have arrived at the conclusion that the introduction of calf lymph is a thing not only permissible, but advantageous, and that it is only an open question in what manner that advantage may best be conferred. Dr. Ballard told us that he was of opinion, and had long been of opinion, that it was not only permissible for public vaccinators to improve their stocks, when they found the humanized lymph failing, by having recourse to animal lymph, but that he encouraged them to do so; and Dr. Stevens told us finally that he did not desire to be understood as disputing any of the conclusions and experiences of Dr. Warlomont on animal lymph, but only as doubting whether it would be possible to introduce it so generally as to meet the requirements of the population when that system was adopted, or whether any attempt to introduce it on a scale sufficiently large would not involve too great an expense. Those, of course, are questions which it peculiarly behooves the Local Government Board to consider, before entering upon a system such as that which has been discussed. I must say that, in the report which I had the honor of presenting to this conference as the basis of discussion, what was advised was not the introduction of

¹ The bag was prepared for me with great care and skill by the Davidson Rubber Co.

compulsory vaccination by calf lymph, but the introduction of a central station for calf lymph, which might be distributed as a means of strengthening the sources from which persons might be vaccinated; and in that I did not go to the extent of saying that every one should have the right of demanding to be vaccinated with calf lymph, but only that the public vaccinators should have adequate supplies of it."

SMALL-POX.

The occurrence of small-pox with a few fatal cases in the District of Columbia, in Philadelphia, and in Worcester makes the subject of vaccination of especial importance at the present time. Systematic vaccination has been resorted to in the District of Columbia to the extent of twenty-four thousand persons (January 31st), and is now in progress at Worcester. It is thought that vaccination and isolation will prove sufficient to avert an epidemic.

In this connection the following report from Bath, Eng., is of interest: "Between the occurrence of the first case of small-pox on July 23d and December 31st, being a period of five months and seven days, a total number of eighty cases were reported. The deaths amounted to eighteen, two of which had not, for special reasons, been removed. Of these deaths twelve were unvaccinated, and four had marks which were equivalent to no vaccination; of the remaining two there was no information. The outbreak occurred and has, with the exception of some half dozen sporadic cases, been confined within certain limits, and so far has not shown any tendency to spread beyond those limits. Nor have those sporadic cases proved the foci of infection which sanitary pessimists would expect; this is attributed to immediate isolation and disinfection. The same results might have been obtained in those streets and courts in which the disease has prevailed had the conditions been the same, but the comparatively total regardlessness of all sanitary precautions, both generally and socially, renders almost futile the effects of isolation and disinfection which have been and are being carried out in the districts affected by the disease, and inasmuch as the inhabitants of these places are of the poorest class, probably in want of proper food and sufficient fuel at this inclement season. So do we find that small-pox has, following its ordinary laws, entirely confined its attack to this class. Not one single case of small-pox among the upper classes has been reported; not one single case of the disease has been reported in the streets and squares and crescents, which are the residence of the upper class, and to which visitors resort."

YELLOW FEVER.

Dr. Joseph Jones, in an exhaustive paper on the Comparative Pathology of Malarial and Yellow Fevers,¹ draws the following conclusions:—

First. As destructive and extensive pestilences, resembling yellow fever, have destroyed the aboriginal inhabitants in former times, when they formed a numerous and comparatively dense population, we are justified in holding that the American continent has been in past ages subjected to wide-spread terrestrial, celestial, and climatic conditions which were hostile to human life.

Second. The experience of the past leads to the belief that such destructive combinations or conditions

may occur in the future, and cause wide-spread destruction uncontrollable by human means.

Third. Yellow fever has, since the advent of Europeans in the Antilles and in North and South America, prevailed at various periods, separated by no uniform intervals, with great violence, and during such periods its area has been widely extended, as in 1878.

Fourth. However perfect the sanitary arrangements and complete the quarantine regulations of cities situated within certain parallels of latitude, it is probable that in seasons of great epidemic influence human agency may fail in the circumvention or arrest of the American plague.

Fifth. In insular, tropical, and subtropical America, one of the most essential conditions for the increase of yellow fever is the accession and crowding of unacclimated persons, natives of the colder regions of America and Europe, in cities or on shipboard. Armies and navies are the great fields of its ravages.

The author then goes at great length into the history of all the yellow-fever epidemics which have visited New Orleans, with their relations to increasing population, climate, etc., and concludes that,—

First. The increase in the number and extent of the epidemics of yellow fever in New Orleans has been intimately associated with the accumulation of unacclimated human beings in the city, and with the increase of commerce and the consequent crowding, and the accumulation of filth and crowd poison in ships and in badly constructed and badly drained and policed habitations.

Second. By its geographical position; by its peculiar topography, situated upon a low alluvial, badly drained, swampy plain, surrounded by large bodies of water; by the exposure of an extended river bank, putrid, stagnant canals and marshes; by defective drainage, sewage, and police; and by its hot and moist climate, New Orleans has been peculiarly exposed to the ravages of yellow fever.

Third. No such marked differences exist between the climate of New Orleans and that of Havana and Vera Cruz as would warrant the assertion that yellow fever is always endemic in the latter two cities, and that at the same time it cannot originate *de novo* in the former. Whilst it is the wish of every true patriot to claim all excellences of position and health for the land of his choice and love, at the same time the future advancement of sanitary science and the highest interest of humanity demand that all causes of disease, whether existing in the soil or climate, should be honestly stated and fully weighed. In sanitary science, as well as in disease and the science of medicine, the proper remedies and preventives can only be fully appreciated by a comprehension of all the dangers and difficulties.

Fourth. Those who hold to the view that yellow fever never originates in New Orleans, but is *always imported*, must at least be forced by the past history of the great epidemics of this city to admit that its climate and situation are such as to admit of the easy lodgment and rapid propagation of the seeds of this disease.

Fifth. Every system which would look exclusively to the defense of New Orleans from pestilence by quarantine is vicious, and destructive at once to commerce and the best interest of the city, in that it leads to the neglect of those sanitary measures which will best promote the removal and eradication of the causes of dis-

¹ Proceedings of the Louisiana State Medical Society, 1879.

ease, and the removal of those physical conditions which promote the rapid spread of destructive epidemics.

Sixth. It may be possible to institute at once a just and enlightened system of quarantine and hygienic rules among the agents and in the vehicles of commerce, and an enlarged and progressive system of sanitation, embracing thorough drainage, abundant water supply, rapid and efficient removal of all excrementitious matter, and the proper elevation and construction of well-ventilated and thoroughly policed houses.

In a minute comparison of yellow fever with malarial fever, the author states that the peculiar phenomena of yellow fever, like those of acute phosphorus poisoning, are due to the nature of the specific poison, and to the character of the changes, which it is capable of exciting *primarily in the blood*, and secondarily in the nervous and vascular systems, and in the nutrition of the various organs.

The chief causes of death appear to be: (1.) The direct action of the febrile poison upon the blood and nervous system, depressing and deranging the actions of the one, and rendering the other unfit for the proper nutrition of the tissues. (2.) The suppression or alteration of the functions of certain organs, as the kidneys and liver, and the retention in the blood of the excrementitious matters normally eliminated by these organs. (3.) The structural alterations of the heart, and consequent loss of power in this organ. (4.) Profuse hemorrhages from the stomach and bowels.

(To be concluded.)

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

MARCH 8, 1880. DR. JAMES C. WHITE, permanent chairman, presided.

IRREDUCIBLE HERNIA.

DR. J. C. WARREN read a paper on the treatment of irreducible hernia. See page 271 of the present number of the JOURNAL.

DR. HODGES said a striking instance of irreducible hernia, which for dimensions might well be compared with the famous one of Gibbon, was for many years exhibited to the successive classes of the medical school by Dr. H. J. Bigelow, in the person of a man who earned his living as a wood-sawyer, and whose hernia must have included most of the movable abdominal contents. It extended below the knees, and was carried without any support. It gave a conspicuous straddle to his walk, but in reality disabled its possessor much less than has been supposed.

The subjects of this affection do not often present themselves for continuous treatment by surgeons. Apparently they get on remarkably well without apparatus other than a suspensory bandage, worn to prevent increase rather than to cure the disease. Dr. Warren's case was an exceptional one in size and an unusual illustration of successful reduction. Fortunately strangulation rarely occurs in irreducible hernia, chiefly because the inelastic character of the fibrous tissues of the rings disappears, as has been pointed out by Cruveilhier and Gosselin, and one of the chief factors in

strangulation is thus removed. Their omental character and partial reductibility make the attacks of inflammation to which they are liable a less serious accident than it would be if the intestine were a larger component part of the protrusion than it ordinarily is.

From the early days of surgery cases have been reported cured by means of long-continued rest, and in any instance which may be fairly termed irreducible the importance of time and confinement to bed cannot be overestimated, no matter what other adjuncts may be brought into requisition. By an irreducible hernia is meant one in which the major part is pretty firmly bound in its place by adhesions, and not such as, after a brief rest in bed, is returned spontaneously, or with little effort. There are some which, although the recumbent position may drain them of a portion of their contents, and make them smaller and more completely reducible than they generally are, must still undergo little change by any compressing measures applicable. Such an instance, recently seen in consultation by the surgeons of the Massachusetts General Hospital, had, by the death of the patient not long after his return home, afforded an opportunity for the examination of the parts involved. A mass of omentum, hypertrophied and of great density, equaling the two fists in size, bulged out from a constricted neck of still greater density, and not more than an inch in diameter. It would be difficult to conceive of the reduction of such a mass, or of its toleration within the peritoneal cavity if it had been possible to return it.

In 1852 attention was attracted in London to some cases of Mr. Bransby Cooper's, in which, by means of a spinal elastic bandage, an air-bag was bound down upon the irreducible tumor, and the whole apparatus having been further reinforced by buckled webbing straps, the air-bag was inflated through a protruding tube, with the gradual result of elongating the adhesions, inverting the sac, and accomplishing a complete reduction of the hernia. In certain cases a plaster-of-Paris cast of the partially protruded mass had been taken, and the further reduction facilitated by a pad constructed on the mould thus obtained.

The varied methods which have been successfully adopted must be practically limited in their application by the comparative infrequency with which the size of the hernia calls for treatment, on account of the discomfort it occasions, as well as by the indisposition and inability of patients to submit to the long confinement necessary to accomplish a satisfactory result.

DR. BRADFORD remarked that this method of compression had also been used in the treatment of enlarged knee-joints; he also said that Scarpa had treated hernia, by compression before the time of Maisonneuve, mentioning the case of a young lady with an umbilical hernia where the compression was made by Scarpa by means of a brass plate.

Sir Astley Cooper advises using a suspensory bandage lacing in front, and getting compression in this way. Mr. Maunder reports a case of irreducible hernia cured by rest in bed, without the cathartics and venesection employed by earlier surgeons. Dr. Bradford also said, "In regard to what Dr. Hodges says about the infrequency of these cases, I know of two women with umbilical hernia of such size as to confine them to bed, and to render doses of morphia necessary for the relief of the colic occasioned by them, and in these cases the treatment spoken of by Dr. Warren would be of great value."

DR. GREENOUGH said that it would be interesting to know whether a hernia existed at the time that the operation for varicocele was performed, a fact which he was unable to state, although when a medical student in Paris he saw the operation performed on this patient, the method employed being to isolate the tumor and then to apply Vienna paste.

DR. FIFIELD remarked that irreducible hernia must be divided into two classes, namely, temporarily irreducible and permanently irreducible, and that they could not be confounded. All irreducible hernia must belong to one or the other class. The important point was to distinguish between the two. Those of the first class were reducible by time, position, starvation, purgation, taxis, mechanical agencies acting from without. Those of the second class were not to be reduced by any agency short of actual dissection, and possibly not always by that.

It had been his fortune to have seen many hernia, both in the living subject and in the dead. And he could bear witness to the dense adhesions of omental and intestinal hernia to the sac (and to these may be added change of form in omentum), forbidding the efficacy of any mechanical appliances excepting the knife. Of the adhesion of intestine to the sac at the ring, it is recorded of an old French operator that he had found it to be so close that, despairing of passing finger, director, or knife under the stricture, he had boldly opened the intestine, and had divided both at a blow. Lawrence speaks of having found adhesion of intestine to sac so intimate that when he had finished the dissection one would have sworn that he had removed a tunic of the gut. To distinguish accurately between these two classes is beyond human skill. Hence one could not hold out a promise to a hernial patient of reduction of his irreducible hernia. Its accomplishment must be the act of fortune, not of judgment or skill. If the hernia be temporarily irreducible, although it may have existed in this state for years, it can be reduced in many ways. If it be permanently irreducible it cannot in any way be reduced.

Temporary irreducibility is the snare between strangulation and non-strangulation always spread for the diagnostician.

Dr. Fifield then made some brief remarks on the operation of Baron Sennin in temporarily irreducible hernia, namely: the rupture of either the external inguinal ring or of some of the inter-columnar fibres, by tearing them with the finger. He had once practiced this with success.

DR. REYNOLDS spoke of using this same method of continued gentle pressure in the reduction of inverted uteri, and suggested that there was a fair comparison between such cases and the hernia described by Dr. Warren. — DR. WARREN inquired if the inverted posture had been tried in these cases of inverted uteri, in connection with rest for a long period. — DR. REYNOLDS thought that it had not.

DR. C. D. HOMANS exhibited a unilocular cyst removed from the left broad ligament of a lady twenty-eight years of age by Dr. John Homans. The patient was married in 1869, and had had four children. The cyst had probably been growing for about seven years. The operation was performed in thirty minutes, the incision being two and one half inches long. There were no adhesions. The weight of the fluid was twenty-five and three fourths pounds, and it was clean and limpid. The weight of the cyst was eleven ounces.

There was no hemorrhage. The pedicle was tied and dropped into the abdomen. The patient is doing well.

DR. HODGES spoke of the ease with which spontaneous fracture may take place in old people and mentioned in illustration the case of an old gentleman of eighty years, in whom a fracture of the femur occurred, no one knew exactly when; the patient was otherwise healthy.

DR. GREENOUGH called the attention of the society to an improvement in the preparation of ointments, which consisted in using vaseline for a base instead of lard. He referred to the usefulness of mercurial ointment as a local application in certain forms of skin disease in which there is much infiltration. The efficacy of this ointment as a dressing is of course most marked in cutaneous affections of a syphilitic origin, but by no means confined to such. The tendency of the mercurial ointment to become rancid and in consequence irritating was an objection to its use, but by preparing it with vaseline instead of lard this difficulty is obviated. The result is a very smooth, elegant ointment of the official strength, a specimen of which he showed. Several other of the official ointments are manufactured in this way, such as the oxide of zinc, acetate of lead, citrine ointments, simple cerate, etc., and they all are very smooth, thoroughly mixed, and do not develop the fatty acids by being kept. He thought this form of the mercurial ointment would be found especially adapted for the purpose of treatment by inunction.

DR. WHITE inquired as to the relative readiness of absorption of lard and vaseline, and also how long these preparations with cosmoline and vaseline have been tried. — DR. GREENOUGH said that the absorption with the vaseline ointment in one case which he had noticed appeared to be rather more speedy than with the old mercurial ointment, but that the preparations had as yet been tested but a short time. — DR. WHITE said, in answer to a question as to whether vaseline becomes rancid, and as to what change takes place in it after keeping for some time, that we do not yet know enough about these petroleum compounds to say what will occur when they are combined with mercury and other substances.

PLACENTA DIMIDIATA.

DR. RICHARDSON showed the specimen, which consisted of two distinct placentae, one being about four and a half inches in diameter, the other three inches. The distance between the two measured six inches. From each ran two arteries and a vein. Near the junction of the two umbilical cords the arteries united; so that the true umbilical cord consisted of one vein and two arteries. Professor Hyrtl, who has written the best monograph on the placenta, has never seen but four cases of this rare form of placental development. In the case which he has chosen as an illustration of this form there are distinct arterial communications between the two placentae. In this case, however, there are no such vessels to be found. Each placenta has its own vessels, which unite and form two distinct cords, which again unite and form a single umbilical cord. Both placentae were of the so-called battledore variety, which is the usual shape observed in this rare form of placental development. The injection in this specimen was made by Dr. W. F. Whitney.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

T. M. ROTCH, M. D., SECRETARY.

NOVEMBER 29, 1879. Sixty-eight members were present, DR. CALVIN ELLIS in the chair.

GLAUCOMA.

DR. WILLIAMS made some remarks on a class of cases, namely, of glaucoma, which were apt to be overlooked by physicians, the correct diagnosis not being made until it was often too late to save the eye, and stated that an early recognition of the very evident symptoms of the disease was exceedingly important.

DR. E. W. CUSHING read a paper on Epidemics in Summer Hotels, which is reserved for publication.

DR. C. E. WING read a paper on Inversion of the Uterus, in which continued gentle pressure was the treatment recommended.

BONY FORMATIONS IN THE EYEBALL.

DR. B. JOY JEFFRIES exhibited three specimens of bony formation in the eyeball.

The first was removed by Dr. F. P. Sprague at the Massachusetts Charitable Eye and Ear Infirmary, from a woman aged thirty-three, who had lost the eye when a child, and wore an artificial eye over the remains of the stump. Recently this had caused much trouble, inflammation, and pain, but without giving rise to sympathetic trouble of the other eye. The remains of the eye were deep in the orbit, hardly noticed. The globe was angular and closely applied over such an irregularly-shaped, bony formation as at first to suggest a foreign body.

The second case was Dr. Jeffries's, a woman twenty-four years old, whose eye was lost when she was a child. The remains were only about half the size of a normal globe, tender and irritated, with sympathetic trouble in the other eye. A bony cup reached forward to the ciliary region.

The third case was also Dr. Jeffries's. A man now fifty-one, when a sailor, in 1867, hurt his eye with a piece of rope. The sight was gradually lost, with exacerbations of pain from time to time. His other eye had troubled him for the last year and a half, and he had marked sympathetic trouble, ciliary redness, photophobia, etc. His injured eye was partly disorganized, extremely sensitive, with great pain in the head, so much so that he doubted whether he should be able to undergo an operation, until he understood that ether would be given. The condition of the other eye, as was anticipated, continued critical, even after enucleation was done. A very solid mass of bone formation was found; spicular extended forward to the ciliary region. The eyeball was quite irregular in shape.

DR. JEFFRIES spoke in general of the formation of bone in the eye. He said that the structure histologically was true bone, though this was doubted many years ago. He believed that when the bone forms so as to come forward and implicate the ciliary region it is a potent cause of the dangerous sympathetic trouble. He regarded the removal of a stump as always indicated when the patient was to go away and be out of the reach of competent surgical assistance, since the insidious sympathetic trouble came when least looked for or expected.

DECEMBER 27, 1879. Eighty-one members were present.

DR. DAVID HUNT read a paper on Harvard University and Medical Reform.

DR. HAMILTON OSGOOD read an interesting paper on Medical Missionary Work in Japan, and showed surgical instruments in use by the Japanese.

OVIARTOTOMY.

DR. JOHN HOMANS showed three ovarian tumors recently removed by antiseptic ovariectomy. One was a unilocular cyst without adhesions; one a dermoid cyst, containing skin, hair, and bone; and one a multilocular cyst. The adhesions in the last two cases had been treated partly by ligatures with silk or catgut, and partly by Paquelin's thermo-cautery. The cases will be reported at length at some future time. DR. HOMANS remarked that the treatment of the pedicle by ligature and returning the stump to the abdominal cavity gave the most brilliant results, the recovery being almost immediate. He showed several temperature charts of cases of ovariectomy, and called attention to their great uniformity, the temperature showing a marked rise to a point between 101° and 103° F. during the first forty-eight hours, and then a fall to normal temperature on or before the fifth day following the operation. In several of his cases there had been absolutely no abdominal symptoms, no pain, tympanites, nor tenderness. He attributed recovery in the great majority of cases to the antiseptic precautions. There seemed to be no more risk in making an incision through the abdominal parieties under a spray of carbolic acid than in making an incision of equal length in any other region; and he thought that ovariectomy, in practiced hands, and done antiseptically, was one of the most successful surgical operations of the present day. He also called attention to the different conditions under which the abdomen was explored during an ovariectomy, and when abdominal section was done for the relief of intestinal obstruction. In the former case the collapse and removal of a large cyst leaves ample space for inspection and manipulation; while in the latter the intestines, distended with gas, crowd out of the opening almost into the surgeon's face, and greatly embarrass his operations. DR. HOMANS alluded to the splendid series of successes of Dr. Keith, of Edinburgh, who had had seventy recoveries consecutively, and has lost but three of his last hundred ovariectomies.

DR. WING asked if the pedicle in the third case was not rather short for the use of the clamp, stating that in a case which he had seen in New York the patient, although she recovered, had become a chronic invalid and opium eater, from pain and tension in the ovarian region, probably caused by the adhesions resulting from drawing the pedicle forcibly outwards, so as to apply the clamp.

DR. HOMANS said that he had also noticed a case of this kind.

— Broca recently discovered a fire in his room by means of localized thermometry, upon which he had that evening been engaged. The firemen could discover nothing, and were displeased at having been called, but Broca insisting that the floor should be taken up at the point at which the thermometer had indicated a comparative rise of temperature, the flame and smoke rushed out from a beam which was in process of slow combustion.

Recent Literature.

Pseudo-Hypertrophic Muscular Paralysis. A Clinical Lecture. By W. R. GOWERS, M. D., F. R. C. P. London. 1879. Pp. 66.

This valuable little monograph presents in a clear and striking form the features of this distressing and mysterious malady so far as they have been investigated, either by others or by the author himself.

The statements are based upon the analysis of two hundred and twenty cases, of which forty-four are now made public for the first time. A number of very instructive figures accompany the text.

Among other clinical facts which are dwelt upon is the extraordinary susceptibility of the male sex, in spite of the fact that the females of the same family, though not themselves affected, remain able to transmit the disease to their male issue.

"The character of limitation to males, and unilateral inheritance from the ovum only, the mother not being affected, but the mother's brother suffering, is seen also in some cases of hæmophilia, and perhaps in no other disease." The reviewer has been reminded by a friend that the same law covers the transmission of color-blindness, and one or two other pathological states.

"Of the two hundred and twenty cases analyzed, one hundred and two were apparently isolated, and one hundred and eighteen were grouped in thirty-nine families."

It is not, as a matter of fact, the increase in size of the muscles which is the pathognomonic feature of the disease, though it has given it its name, but the history and distribution of the muscular affection. "The condition of enlargement may pass into, and even be preceded by, diminution." Even the enlarged muscles are, the author believes, always weak.

Like most of the other writers who have investigated them, Dr. Gowers believes that the changes observed in the spinal cord are not the cause of the disease but secondary or accessory features; and he inclines to the view that it is really due to a "perverted tendency of development inherent in the germinal tissue of the muscular system." Structurally the tissue thus developed deserves the name of myolipomatous, and Dr. Gowers records a case of the formation of a similar tissue within the vertical canal (not in this disease, to be sure), showing that it is capable of developing of itself, apart from any nervous influence, or from any of the causes which might be supposed to excite the changes met with in ordinary cases of the disease.

With regard to treatment, but little new or encouraging is recorded: arsenic, cod-liver oil, and phosphorus seem to have had some influence in temporarily arresting the advance of the affection, and the value of systematic exercise is especially dwelt upon. The prognosis is better for girls than for boys.

J. J. P.

Notes on Diseases of the Testis. By SAMUEL O'BORN. London: J. and A. Churchill. 1880.

In this little work, comprising only one hundred and seventeen pages of twenty-eight lines each, the author has undertaken to describe the diseases of the testis.

To give an idea of the inadequate way in which the subject is treated, we need only point out that the chapter devoted to syphilitic sarcocele is limited in extent to six pages, in the course of which not a single authority is quoted. The style of the book is fairly exemplified in the following sentence: "The testicle may be affected by syphilis, as may any other organ of the body, those parts becoming affected which are the more weak, and consequently the less likely to withstand the syphilitic virus; for it is in those persons who, if affected with gonorrhœa, develop secondary disease of the testis, would, if affected with syphilis, develop subsequently syphilitic sarcocele, showing that the organ is weak, and necessarily liable to become affected."

Short as this book is, time devoted to its perusal can but be wasted.

Skin Diseases, including their Definition, Symptoms, Diagnosis, Prognosis, Morbid Anatomy, and Treatment. A Manual for Students and Practitioners. By MALCOLM MORRIS, Joint Lecturer on Dermatology at St. Mary's Hospital Medical School, and formerly Clinical Assistant, Hospital for Diseases of the Skin, Stamford Street, Blackfriars. With Illustrations. Philadelphia: Henry C. Lea. 1880.

This little treatise of three hundred and twenty pages is a well-meant effort to condense a somewhat extensive subject, and contains much that is of value. Its contents, however, consist of twenty-four separate chapters representing lectures, a most unsatisfactory arrangement for a text-book. It is very true that these are changed in form, and stripped of the verbiage which serves to pass the time during which isolated truths are crystallizing in the hearer's mind; but for all that, their origin is evident, and such an arrangement is unsystematic and unscientific. Thus, of the six classes into which the writer subdivides the diseases of the skin proper, Class I. Exudations, monopolizes fourteen chapters, in which we find scarlet fever, measles, variola, typhus and diphtheria, verruca necrogenica, framboesia, syphilis, and ulcers. Class II. comprises Vascular Affections; Class III. Neuroses; Class IV., Hypertrophies; Class V., Atrophies; Class VI., Neoplasms. The writer has certainly, however, given in a small compass a large amount of well-compiled information, and his little book compares favorably with any other which has emanated from England, while in many points he has emancipated himself from the stubbornly adhered to errors of others of his countrymen. He has actually separated prurigo, the disease, from pruritus, a symptom, although not yet fully alive to the fact that pruritus *scutellus* has nothing to do with lice, while pruritus from lice is peculiar to no age. Since he recognizes a chloasma "uterinum," we are surprised to see chloasma still retained as the synonym of the parasitic disease tinea versicolor. His adoption of the terms "fibroma" and "xanthoma" is an advance, but under the head neoplasms we have not been accustomed to seek for clavus, tylosis, verruca, and cornu cuticæum. Yet in spite of inaccuracies in classification and a somewhat non-conspicuous nomenclature, there is certainly excellent material in the book which will well repay perusal, and, as a whole, we recommend it, though rather to the practitioner than to the student.

Medical and Surgical Journal.

THURSDAY, MARCH 18, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, OSGOOD AND COMPANY, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, OSGOOD AND COMPANY, BOSTON, MASS.

MODEL SCHOOL-HOUSES.

THERE certainly can be few matters of more vital importance to the physical welfare of the community than the sanitary condition of the public schools in our large cities. Aside from the fact (which is everywhere recognized by the profession, at least) that, notwithstanding all precautions to the contrary, these institutions constitute one of the most formidable agencies in the spread of contagious affections, it is not perhaps so fully appreciated on the part of the public to how great an extent their defects, in a hygienic point of view, are concerned in the causation of other forms of disease, often of a constitutional nature, and followed, sooner or later, by the most serious results. Any effort, therefore, which looks towards a reformation in the construction of buildings thus occupied should meet with the greatest possible encouragement from all enlightened citizens, and hence it is to be hoped that the recent competition for prizes for the best plans of model school-houses, offered by the *Sanitary Engineer*, and the report of the committee appointed to award these prizes may eventually be productive of much good. Now that the board of education in New York have seen fit, in their inscrutable wisdom, to dispense, in the future, with the services of a supervising architect of public-school buildings, any alterations to be made in the old ones, as well as the construction of new school-houses, are apparently to be left to the direction of the members of the board (who may or may not be the most competent persons for attending to such kind of work); it can, at all events, do no harm that they and similar bodies in other places should have the means of becoming acquainted with the most important requisites necessary for such edifices; and this the competition and report alluded to have now supplied to the public in a more prominent, forcible, and practical manner than has previously been done.

The committee of award in this competition was selected from men of the highest ability and standing, on account of their peculiar fitness for the position, and consisted of Mr. George B. Post, the architect, of New York; Dr. John S. Billings, of the National Board of Health; Hon. John D. Philbrick, late United States commissioner of education at the Vienna and Paris exhibitions; Professor William R. Ware, of the Massachusetts Institute of Technology; and Dr. Cornelius R. Agnew, of New York. According to the terms of the competition, it was demanded that the school building should accommodate eight hundred pupils, half of either sex; that it should be erected on a lot one hundred by one hundred feet, fronting north

and surrounded by buildings of average city height; that it should be of fire-proof construction, with separate entrances and class-rooms; that the class-rooms should accommodate from fifty-four to fifty-six scholars, with a separate desk for each one; and that there should be principals' and teachers' retiring-rooms, and one assembly-hall only. The special features which were considered by the committee in making their awards are as follows: (1) convenience of arrangement for school purposes; (2) security against fire and facility for egress; (3) distribution of light; (4) ventilation and heating; (5) drainage and other sanitary appointments.

They examined nearly one hundred plans altogether, and finally arrived at a unanimous conclusion in regard to their merits. Of the ten designs which secured the highest approval, that by Arthur T. Matthews, of Oakland, California, was awarded the first prize, of \$250, and that by Samuel F. Thayer, of Boston, the second prize, of \$125. Three other Boston architects were also among the successful competitors. The committee declare in their report, however, that none of the plans submitted were altogether satisfactory, but add that it is probably impossible, under the conditions imposed upon the competitors, to produce a plan which could be recommended in all respects as one to be followed in the actual construction of school-houses. These conditions were purposely made very difficult to fulfill in order the more forcibly to demonstrate how utterly inadequate and ill adapted to their purpose are most of the public schools in New York, where ordinarily two thousand children are crowded into a building erected upon a lot of one hundred by one hundred feet, and surrounded on all sides but one by dwellings of many stories in height, which are frequently hot-beds of contagion. Hence the committee are at pains to state that they do not recommend the plans to which they have given awards as being the best designs for a school building, but only as the best plans for a school building to be erected in a huge box, lacking one side and without a top, the sides of which box are about sixty feet high; which seem to be the conditions under which school buildings have been erected in New York, and in which from fifteen hundred to twenty-five hundred children have been crowded.

The description given by them of Mr. Matthews' plan, which was awarded the first prize, is in part as follows: "Light and air are supplied from a rear interior court, which communicates by two archways with the street, and thus insures a constant circulation of air throughout the interior of the building. As there are no openings in the side walls, there is no chance of fire or contagion being conveyed from adjoining houses, or of annoyance from neighboring nuisances. Above the second floor there are really two distinct buildings, and this would be another cause of security from fire, as well as a means of isolation. The very best light is also thereby secured, both for the assembly-room and for all the upper class-rooms. The assembly-room is located on the second floor, and much ingenuity is shown in utilizing its space to accommodate the pupils. The water-closets are placed

in the basement, which is objectionable. The classrooms are not too large, and are accessible."

The committee are of the opinion that a public-school building to be erected in a large and densely populated city should possess the ten following qualifications: (1.) At least two adjoining sides of the building should be freely exposed to light and air, for which purpose they should be not less than sixty feet distant from any opposite building. (2.) Not more than three of the floors should be occupied for classrooms. (3.) In each class-room not less than fifteen square feet of floor area should be allotted to each pupil. (4.) In each class-room the window space should be not less than one fourth of the floor space, and the distance of the desk most remote from the window should not be more than one and one half times the height of the top of the window from the floor. (5.) The height of a class-room should never exceed fourteen feet. (6.) The provisions for ventilation should be such as to provide for each person in a class-room not less than thirty cubic feet of fresh air per minute, which amount must be introduced and distributed without creating unpleasant draughts, or causing any two parts of the room to differ in temperature more than two degrees, Fahrenheit, or the maximum temperature to exceed seventy degrees, Fahrenheit. This means that for a class-room to contain fifty-six pupils twenty-eight cubic feet of air per second should be continuously furnished, distributed, and removed during school sessions. The velocity of the incoming air should not exceed two feet per second at any point where it is likely to strike on the person. (7.) The heating of the fresh air should be effected either by hot water or by low-pressure steam. (8.) The fresh air should be introduced near the windows; the foul air should be removed by flues in the opposite wall. (9.) Water-closet accommodation for the pupils should be provided for on each floor. (10.) The building should not occupy more than half the lot. Special attention is called to the necessity of sufficient light in the school-rooms, and it was on account of defects in this essential feature that the great majority of the plans sent in for competition were rejected.

In concluding their report the committee express the hope "that those interested in the sanitary welfare of New York will give their attention to this problem, which, to be properly solved, will require some legislation, and a change in the present methods of selecting school sites and of erecting school buildings." It is very much to be wished that the attention directed to this important subject by the recent competition and the excellent report of the committee of award may act as leaven in the public mind, so that in process of time such a revolution may be wrought in these matters as to make every single school building what it ought to be, a model in all its arrangements.

— Dr. F. P. Foster now edits the *New York Medical Journal*, vice Dr. Hunter, whose increasing practice compelled him to resign the editorial chair.

MEDICAL NOTES.

— According to the *Philadelphia Medical Times*, the regular profession in Camden County, New Jersey, has been very much exercised of late. Some time ago the county erected an insane asylum, and appointed a committee to manage it. This committee, not being well posted in medical matters, suddenly appointed a homœopath as superintendent. This of course isolated the institution from all the benefits of regular medical skill, and from all the great insane asylums of the United States. After a six months' trial the experiment was decided to be a failure, and a regular physician was placed in charge. The homœopath, who is said to have been a person of more than average ability, stated to the board, in his defense, that he had administered the homœopathic treatment, *similia similibus curantur*, to a person with epilepsy, until the patient became so bad that he had a thousand fits in six weeks. Then, by resorting to regular applications of chloroform and ice to the spine, the fits were stopped.

— In the *Medical and Surgical Reporter* we read that two Baltimore physicians, Drs. Clagett and Walls, were sued for alleged malpractice, damages ten thousand dollars, and the case has been recently tried. It related to fracture of the arm. Dr. Walls explained its nature and the treatment adopted so clearly that at the conclusion of his testimony the counsel for the plaintiff arose and said, "The plaintiff takes pleasure, as does his counsel, in saying that this suit was brought under a misapprehension of the facts, and he is so impressed with the doctor's free, full, and candid explanation of the whole case that he authorizes his counsel to apologize to the doctor, and to enter a *vol. pros.* in the case."

— In a letter to the *Philadelphia Medical Times* of February 14th, Dr. Fothergill makes a sharp reply to English criticisms upon his remarks concerning the social position of practitioners in that country. He calls the matter "a tempest in a tea-pot," and complains of unfairness on the part of the editor of the *British Medical Journal*.

— Dr. Laurence Turnbull having claimed priority in the administration of ethyl bromide, Dr. R. J. Levis, of Philadelphia, who is making large use of this ether, shows, in a paper in the *Philadelphia Medical Times*, that Nunceley, of Leeds, England, experimented with the anæsthetic in 1849, and in 1865 frequently administered it to patients undergoing surgical operations.

— Sir William Gull began his medical life as a bottle washer in the drug-room of Guy's Hospital. His father was a laborer, and tilled a small plot of ground adjoining the hospital.

NEW YORK.

— A member of the American Public Health Association has just presented to the legislature a memorial, signed by Dr. Willard Parker, Howard Potter, the Rev. Dr. Bellows, William E. Dodge, A. A. Low, Dr. Cornelius R. Agnew, Theodore W. Dwight, Peter Cooper, Abram S. Hewitt, Chancellor Crosby, and

other influential citizens, recommending the establishment of a state board of health. After mentioning the fact that New York is almost the only State in the Union which has no public registration of births, marriages, and deaths, and that in only three or four of its cities is there provision for any sort of a record of these, the benefits which would arise from the existence of an efficient state board are set forth. The methods which it is proposed to adopt comprise popular instructions and explanations, the publication of brief reports on the leading sanitary questions of the day, and the skilled investigation of those subjects which particularly affect the public health. The cost of such a board is estimated at five thousand dollars per million of the population.

The value of a correct registration is well illustrated in a case which is now attracting considerable attention. A German lady, after having given birth to two children, a boy and a girl, in New York, where her husband became a naturalized citizen, returned to her native land. She now writes to the New York registrar of vital statistics for copies of the birth certificates of her children, as, unless these can be produced, one of them is in danger of being drafted into the imperial army, and the other is unable to marry, because the German authorities announce that they have no proof that the former was born in America, or that the latter *was ever born*. Another similar instance has also come to light. A family to whom a daughter was born in New York, and who have since gone to Austria to reside, have written for the birth certificate of the child, as they are desirous of sending her to school, and she cannot be admitted without this. Dr. Nagle, the deputy registrar of vital statistics, says that scarcely half the births in the city are registered, an oversight which in after-life may cause much trouble and annoyance to the children of foreigners naturalized here.

—Dr. Nagle reports that during the year 1879 two hundred and fifty-five deaths in New York were directly attributable to intemperance, the immediate cause of death being classified as follows: Fracture of the skull, two; congestion of the brain, nine; nephritis, forty-two; delirium tremens, eighteen; alcoholism, seventy-one; and pneumonia, nineteen. Of the individuals thus dying, one hundred and five were natives of Ireland, eighty-four of America, thirty-five of Germany, ten of England, four of France, and one of Scotland.

—The Commencement of Bellevue Hospital Medical College was held at the Academy of Music on March 3d, and there were one hundred and forty-two graduates. The address to the class was made by Mr. Chauncey M. Depew, and the valedictory address by William C. Stone, of Massachusetts.

—At the second meeting of the Academy of Medicine in February, a paper was presented by Dr. Henri Nachtel, of Paris, on Medical Night Service as it is now in Operation in Paris and other European Cities. Prof. T. Gaillard Thomas also read a paper, his subject being The Anatomy, Physiology, and Pathology of the Female Perinaeum. Both papers at-

tracted unusual attention on the part of the profession, and a special committee, with Dr. J. W. S. Gouley as chairman, was appointed to investigate the former subject, and report at an early date as to the practicability of establishing a night medical service in New York. At the first meeting of the Academy in March, Dr. Henry D. Noyes exhibited a case of blepharo-plasty, in which the eyelid was formed by a piece of skin transferred from the chest, after which Dr. C. E. Billington read a paper entitled, Forty Attested Cases of Diphtheria, with Remarks on Diagnosis and Treatment.

—The bill of Mr. Bergh to prevent vivisection has been reported adversely by the judiciary committee of the Assembly at Albany, and the report having been agreed to by the house the bill is killed. This desirable result has no doubt been brought about in great part by the personal exertions of Prof. John C. Dalton, and by the remonstrances which were presented to the legislature on behalf of the New York State Medical Society, the Medical Society of the County of New York, the New York Academy of Medicine, the New York Medical and Surgical Society, the New York Pathological Society, the Albany Academy of Medicine, the Buffalo Medical Association, the Rochester Medical Society, the Brooklyn Anatomical and Surgical Society, the Elmira Academy of Medicine, the College of Physicians and Surgeons, Bellevue Hospital Medical College, the Medical Department of the New York University, the Albany Medical College, the Medical Department of the University of Buffalo, the Long Island College Hospital, and the College of Medicine, Medical Department of Syracuse University.

—At the last meeting of the County Medical Society, Dr. C. R. Agnew exhibited a simple audiphone which a patient of his had constructed, and which had proved much more efficient in this case than the more elaborate gutta-percha ones. It consisted merely of a Japanese fan bent to the required shape, coated with shellac, and bound with a metallic rim. The doctor was not prepared to say how it might answer in other instances.

ST. LOUIS.

—Missouri is again making its contribution to the medical ranks. On the 2d of March the College of Physicians and Surgeons of Kansas City graduated seventeen young men. On the same evening the College of Physicians and Surgeons of St. Louis held its first commencement, conferring the degree of M. D. upon five aspirants. March 4th the Missouri Medical College gave diplomas to one hundred and fifteen graduates. The valedictory address was delivered by Dr. G. M. B. Manghs. The address was so much admired that at the request of the students it will be published in pamphlet form. March 5th, the St. Louis Medical College graduated forty-one of its scholars. The large fees of this college and the severity of its course diminish its numbers, but it is certainly endeavoring in good faith to raise the standard of medical education in the West. Dr. J. T. Hodgen delivered the

valedictory, in which he stated that more than one half of those being graduated had been three years in the college. Upon examination we learned that eleven had attended three full winter, spring, and summer courses, nine months in each year; twenty-two had attended three winter courses of the college, and five had been practicing previous to entering the college.

The college has adopted the following plan, conformity to which is obligatory upon all entering it: There shall be a graded course of three full winter sessions of five calendar months each; admission to the second and third years of the course to be obtained only upon examination in the subjects of the previous year or years. Fees for the course of instruction necessary for admission to examination for a degree, \$275, namely, matriculation fee \$5, and fees of three years \$90 each. The graduation fee is abolished.

—On the 4th of March the Alumni Association of the St. Louis Medical College held its annual banquet. A number of happy responses to toasts were given, among which may be mentioned one by Dr. John Green to Student Life, one by Dr. William McCandless to Woman, and one by Dr. Case to the Class of 1880.

MEDICAL ADVERTISING.

—“Nor give certificates recommending mineral waters, patents, or medical preparations, or the like.” (New Code of Ethics of Massachusetts Medical Society.) In obedience to the rule cited above, should not the members of the society, whose names appear in such advertisements as are on pages 6 and 7 of the JOURNAL of March 11th inst., cause their names to be removed therefrom at once? INQUIRER.

LITERARY NOTES.

—Walsh's Physician's Handy Ledger seems to be one of the most convenient books of the kind in the market. On two pages of this ingenious ledger may be recorded the visits to an entire family for one year, — their nature, the charges therefor, the gross amount due, and amounts to be credited. The Physician's Call Book, which accompanies the ledger, is equally useful.

—Early Medical Chicago, by James Nevins Hyde, M. D., is a very readable and interesting historical sketch of the first practitioners of medicine in Chicago, and includes the present faculties and graduates, since their organization, of the medical colleges of that city. The book bears evidence of much labor, is well written, handsomely gotten up, and illustrated with engravings of leading medical men and college buildings; a very valuable possession to those interested in the history of medicine in the United States.

—The Regulations for the Government of the United States Marine Hospital Service, issued by the Government Printing Office under the supervision of Dr. J. B. Hamilton, is a neat pamphlet of 146 pages, with index. It presents the regulations for the government of the marine hospital service,

the collection of hospital dues, and application of the funds thus resulting for the relief of sick and disabled seamen. These rules went into force on the first of January, 1880. The pamphlet, moreover, gives all possible information concerning the character of the service, its organization, relief stations and districts, duties of officers, purveyors, and stewards, boards of discipline and inquiry, transportation of sick seamen, and much other interesting matter.

—We acknowledge receipt of the Transactions of the state societies of Illinois, Pennsylvania, and New Hampshire for 1879. They contain papers of marked interest. We note especially the remarkable historical obituary of the late distinguished ovariotomist, Washington L. Atlee, of Pennsylvania. His early struggles, the obloquy cast upon him by such of his fellows as condemned ovariotomy (and at one time they were a majority), his courage and perseverance, and his own story of his gradual but thorny progress in the face of bitter opposition to his operation, form one of the most stirring and absorbing medical sketches we have ever read.

In the New Hampshire Transactions the eloquent paper on Medical Ethics, by Dr. George B. Twitchell, of Keene, nephew of the well-remembered Dr. Amos Twitchell, is a timely argument in favor of a proper code of ethics for the regulation of the conduct of physicians.

Disclaim.

SEA-SIDE ETHICS: A REPLY.

MARCH 10, 1880.

MR. EDITOR, — Yesterday afternoon, for the first time, I saw the article on Sea-Side Ethics, and recognized the letters quoted as mine. I visited the patient several days in Manchester, in June, 1878, but did not seek the case. My letters were in reply to his, and I have not seen the gentleman since June 23, 1878, though as he lives in Roxbury and has his place of business in Boston, I could easily have done so if I had been actuated by the sentiments attributed to me in the aforesaid article.

I am sure the members of our profession whose friendship I have had for the past twenty-five years know I am not a pirate.

I inclose two letters received by me twenty minutes after the reading of your article, and I should like to have you publish them.

Very sincerely yours,

HALL CURTIS.

GREENSLOPE, ROXBURY, March 8, 1880.

TO DR. HALL CURTIS, Boston, Mass.

MY DEAR SIR, — My attention has been called to an article in the Boston Medical and Surgical Journal of March 4, 1880, headed Sea-Side Ethics, which has doubtless fallen under your notice before this, and, as it relates solely to you and to me, seems to call for an explanation from me to you.

The writer says, “The portion of correspondence now copied fell into the hands of Mr. A.’s family physician.” I wish to contradict this statement, and in explanation to say, that at the time I called my family physician (July 1, 1878) I informed him of my attack

in June at the sea-side, and of my calling you, and of your treatment and advice; the latter I showed him. His only comment then was, "I do not agree with him."

I have had no occasion, that I recollect, to call my family physician, nor have I had any other medical advice but yours since July, 1878, until January 2, 1880, at which time I again had an attack—similar to though much more severe than the one I had at the sea-side, in June 1878. My family physician was then called, and I was under his treatment until the latter part of February.

About January 18, 1880, in conversing about my case with my family physician, he asked me to let him see the prescriptions and advice given by you in June, 1878, and I handed them to him as an entirety, supposing he wished to use them professionally (as he would have called you in consultation, could he have seen you in person), and did not for a moment suppose he would be so far guilty of committing a breach of confidence as to use the correspondence to charge you in the first sentence of his communication with having transgressed the "Golden Rule;" and although in the same sentence he refers to you as an *unintentional* sinner," before he closes his communication he charges you with being an "*intentional* sinner," which, allow me to say, I *do not*.

I very much regret *now* that I allowed my family physician even to *see* the communications, and trust you will do me the justice to believe I would not have done so, had I for a moment supposed they would be used against *you*; and I can only add that I have done what I could to vindicate your cause in a letter to my family physician, a copy of which I enclose, and of which you are at liberty to make such use as you may think best. Very truly, GEORGE WOODS RICE.

GREENSLOPE, ROXBURY, March 8, 1880.

TO DR. B. E. COTTING, ROXBURY, MASS.

MY DEAR DOCTOR.—My attention has been called to an article in the Boston Medical and Surgical Journal of March 4, 1880, headed *Sea-Side Ethics*, in which mention is made of a prominent Boston physician who passed his summer in the year 1878 near by ———, for "*pleasure and profit*;" and copies of certain prescriptions and letters written by the aforesaid physician are quoted which were addressed to one whom I know to be a patient of yours, for the reason that the prescriptions were given *to me* and the letters quoted were addressed *to me*, and *both* are now in my possession. Now, as these prescriptions and letters have never been out of my possession, except when *you* asked me to let you take them, about January 18, 1880 (at which time you were attending me professionally for an attack which, I have reason to believe, from the article in question you supposed to be a severe cramp in the hypochondriac region), I am not left in doubt as to who the *author* of the communication is; and as I have always treated you, both as my friend (as I well know you to be) and as my medical adviser, with all frankness and candor, I *do*—sire to do so now, and to say to you that I consider the use you have made of the prescriptions and letters which *you* asked to borrow (as I supposed for *professional purposes only*) as *indefensible*, and am astonished that my good physician should have used *me* and *my case* to make an unjustifiable attack upon one of his own profession, who, from my acquaintance with him, *I am* satisfied intended no breach

of "code or professional rules," as he continued the medical advice *only* at my request, and not with any view to his *own profit*. You say, "The portion of the correspondence now copied *fell* into the hands of Mr. A.'s family physician." *This is not so*; it was requested by you of me, and you were bound to treat it, as I had every reason to believe you would, *in confidence*, and you have placed me by your communication in a very unpleasant and unjust position as regards the "prominent Boston physician." Let me, first, correct a statement made by you, near the beginning of your communication, where you say, "The second day he volunteered a call." *This is not so*, as he made the second day's visit at *my* request. You lay great professional stress upon his course, and make an unjust charge against the Boston physician because he continued to give me professional advice after it became known to him that I had been treated by my family physician after my return from the sea-side. Let me say that the *only* treatment which I recollect to have received from you, when called July 1st, was the injection of morphine subcutaneously, and there seemed to be no better course left to me *then* than to continue to take the advice of one who I think (as you seem to) was "*so much interested*" in my case as the prominent Boston physician was. As you borrowed of me, at the same time with the before-mentioned papers, the prescription of another Boston physician (not spending his summers at the sea-side), whom I had consulted at his own office for a similar attack, just previous to my calling in the physician at the sea-side, why did you not call him to account in the same article for having given me professional advice without consulting with you, *when he knew* that you were my family physician? *Professional jealousy* seems to me to be the basis of this unjustifiable attack, and has led you to betray the confidence of one who, from long acquaintance with you, had every reason to expect very different treatment. Has this monster "*professional jealousy*" attained such growth that the sick are not to be treated, when temporarily out of the reach of their family physician, by a Boston physician spending his summer at the sea-side until he consults the family physician either by mail or telegraph? From the tenor of the communication one certainly has a right to draw such an inference. If your communication falls under the eye (as it doubtless will) of the prominent Boston physician, without any explanation from me, could I reasonably expect to receive medical advice from him, were I needing such advice while stopping at the sea side? I certainly should not expect it, and in justice to myself shall write the Boston physician an explanation of the case, and send him a copy of this letter.

Very truly, GEORGE WOODS RICE.

EFFECTS OF THE ADVOCACY OF THE PROPOSED MEDICAL LAW.

MR. EDITOR.—The following, as one of the effects of the advocacy by members of the profession of the proposed law to regulate the practice of medicine in this State, may interest some of the readers of the JOURNAL.

The Boston Post of March 12th, in an editorial advocating the petition for the admission of homeopathic practice into the City Hospital, which the city government of Boston will soon be asked to consider, has the following:—

"If homœopathy meant empiricism or superscientific practice, it would be the duty of the city to exclude it from its institutions. . . . The allopathists do not maintain any such thing. In their movement for the establishment of a medical board they were willing that the homeopaths should have a representation according to numbers, a concession which of itself furnishes a very strong argument why the forthcoming petition should be granted." M. M. S. S.

EAST BOSTON ETHICS (NEW CODE).

MR. EDITOR, — Dr. A. informed me that he had visited an interesting case that evening. The patient had been seen that morning and the day before by Dr. B., but he was told that the latter had been discharged; consequently he gave his opinion and prescribed. I informed Dr. A. that I was the physician in charge, and had not been notified that any change was desired. As Dr. A. did not suggest a cure for my "wounded feelings," I told him to go on with the case. Two days have passed, and neither the family nor the man who called Dr. A. have notified me that I am not wanted. Is Dr. A.'s course in conformity with Section IV. of the code, when it speaks of "rules of honor and courtesy"? ETHICS.

MEDICAL ETHICS.

BY JAMES O. WHITNEY, M. D., FAWTUCKET, R. I.

A FEW years since, being in conversation with a medical gentleman of New York regarding this topic, he said, "Medical ethics, — what are they but the rules that govern gentlemen applied to our profession?" Clearly this is as good a definition as can possibly be given in general terms, and one who proposes to be a *gentleman* will instinctively observe them, yet no doubt it is wise to have rules in detail.

The writer of Sea-Side Ethics, in the JOURNAL for March 4th, had a clear case of violation of the rules as printed for the Massachusetts Medical Society, and it was his duty to have brought the offender to trial.

I once delivered with forceps the patient of another, also an adherent after-birth, at his request. A year lapsed, and not being paid I suggested this fact to the one I had aided out of a vexatious and dangerous case. The reply was, "Oh, I guess it is not worth your while to make out a bill." The idea was to give me to understand that the patron did not pay his bills. However, I at once sent the bill, and was paid, being informed also that Dr. — was paid immediately on the patient's recovery. The author of Sea-Side Ethics says, "It reveals the most extraordinary conduct on the part of a prominent physician, brought up, and for many years mingling with, the most eminent and honorable members of the profession." I think his case reveals the inherent man; if with all these surroundings he did so demean himself, what would he not do if left untrammelled? I never have seen anything in the conduct of the man I aided to lead me to think his undertaking to defraud me of a fee was exceptional, but many things to confirm the impression that he would repeat the offense. Perhaps the writer of Sea-Side Ethics holds with the suggestion made in an edi-

torial in the JOURNAL upon this topic, not long since, that rules are not enforced by the societies. This had a practical illustration in this State in 1878. Charges were filed and examined by the board of censors. The accused admitted them, yet the report to the society was, "Not sustained."

LETTER FROM PHILADELPHIA.

BOGUS MEDICAL COLLEGES.

THE prestige of Philadelphia as a great medical centre, and the reputation of her well-known schools has suffered greatly for many years by the action of unprincipled men, who set up pretended universities in order to sell diplomas granting degrees *in absentia*, or for merit (!), attendance at the college not being compulsory. This disgraceful fact is now generally understood and properly appreciated throughout Europe, as well as this country, and the holder of a Philadelphia diploma must therefore expect to have it scanned very closely when he goes among strangers. The University of Pennsylvania has been especially victimized by establishments calling themselves "the Pennsylvania University" and "the University of Philadelphia, Pennsylvania," the proprietors of which established agents in all the great centres of civilization for the sale of Philadelphia diplomas. The strangest part of it all is that the colleges and the medical profession have appeared to be utterly helpless, being entirely unable to stop the traffic. If, after a world of trouble, a legislative committee were made to look into the case, and abundant testimony secured (such as selling diplomas to ignorant negroes and to minor children), even if the committee reported in favor of rescinding the charter, then the parties would either obtain in the courts a stay of proceedings, or else would allow that charter to go by default, and simply take another one from their pockets (bought cheap from some defunct college), and go on as before, only a little more cautiously for a time. The crime against society is such a flagrant one, and is so plainly opposed to the best interests of the social life of the community, that the public press has volunteered to come to the assistance of the profession, and lend its powerful influence towards removing this reproach. The mayor of the city, Hon. Wm. S. Stokely, has also interested himself in the matter, and whenever letters are received from abroad (which of late has been less frequent than a few years ago) making inquiry as to the status of these bogus institutions the desired information is always sent, and the letter and its reply are duly published in our daily papers.

Owing to the enterprise of one of our morning papers, the *Public Record*, another diploma-shop has been dragged reluctantly from the obscurity it appeared so eminently fitted to adorn, and has had its modest and retiring disposition outraged by an exposure of its methods to the public, thus giving them a good deal of gratuitous though unsolicited advertising. A few days ago, two young men, being attracted by the prospectus of the college (!), called upon the dean, the Rev. T. B. Miller, M. D., etc., in order to ascertain the requirements for a degree. He informed them that the diploma for a doctor of medicine would cost about one hundred dollars (and that, having three charters in his possession, they could select the one they preferred);

they need not attend the lectures, and could begin to practice right away. The latter possibility was assured to them by a certificate signed by the dean, for which they paid twenty-five dollars, which was also the first installment upon the price of the diploma. They also had an amusing lecture on how to write a prescription, by the entertaining professor, who also gave one set of tickets for lectures that were supposed to have been delivered the last course, which had just closed. The young Æsculapiuses then left, promising that the professor should hear from them again the next morning; which promise they faithfully redeemed. One being the city editor and the other a reporter of the *Public Record*, they published in the morning edition of the paper a full exposé, which excited a good deal of comment, and which since has been widely copied into other journals. The most unpleasant part of the affair is that the three men who appear prominently in connection with this discreditable business are all ministers in good standing, belonging to an orthodox Christian denomination, and all occupying pulpits in this city. A committee of this religious body has been investigating the conduct of these men since the exposure, but has not yet reported its conclusions. The dean has resigned from the institution, but will probably be held accountable before the courts. The following is one of many illustrations of the manner of working these establishments:—

Living in this city is a man named William B., who is a mental unfortunate, and his family state that while he was an inmate of the Pennsylvania Hospital for the Insane they obtained for him a diploma from "The Philadelphia University of Medicine and Surgery." He was a student at the university when it was on Ninth Street, near Spruce, and afterwards his mind became impaired, but his relatives, having paid the institution seventy-five dollars, thought they might as well have the diploma, and sent for it and got it.

This diploma was signed by W. Paine, and is an exact copy of those issued by ex-Dean Miller's institution.

ACADEMY OF NATURAL SCIENCES.

At the last meeting of the Biological and Microscopical Section of the Academy of Natural Sciences, Dr. Carl Seiler continued his illustration of microscopic methods. The speaker took up the subject of injecting with colored fluids for the purpose of throwing into bold relief the courses of the blood-vessels. The only colors which had thus far been very successfully used were blue and red, of which Prussian blue and carmine, respectively, were the bases. Opaque mineral colors are not good, as they render the vessels non-transparent, and obscure all the neighboring structures.

Dr. Seiler exhibited sections under the microscope prepared from the lungs of cattle affected with pleuropneumonia, cut from specimens kindly furnished by Dr. Gadsden, which showed the peculiar alterations undergone by the lung tissues in the course of the disease.

Mr. J. A. Ryder called attention to a most extraordinary and hitherto unknown type of sponge, from the Chesapeake Bay, whose position in the animal kingdom, as far as he was able to predicate from the single specimen in his possession, was quite unique. It was found to possess features met with in no other known species. The surface was covered with prominent delicate, transparent funnels, which led into cavities appar-

ently lined with a single layer of cells. There were no fibres, no spicules, but instead the animal was composed of cavities whose walls were structureless membranes. Its position in the system will be below any other known sponge except the curious *Physemata*, described by Professor Haeckel, and about which there has been so much dispute.

WEATHER AND HEALTH.

The winter of 1879-80 has been with us the mildest remembered; and the record of the weather for the past ninety-one years shows that the present winter is the warmest we have had during that period. The average temperature of the winters during that long time was 31.67°, while the average temperature of the past winter was as high as 38.65°. It would seem that such warm weather during the winter months would be injurious to health, but the statistics of deaths for the months of February, 1879 and 1880, prove that such is not the case this year. During that month last year it rained but twice, the other storms being snow; in the same month this year it rained on six different days, the amount of water falling being nearly double what it was the year previous.

The temperature during that time was, on an average, nine degrees warmer than during the corresponding time of the previous year, yet in 1879 the number of deaths was 1446, while in 1880 the number was 1211. The warm weather has had an effect on vegetation. Dandelions, trailing arbutus, and kindred plants are in full bloom, and trees are beginning to bud.

In contrast to general expectation, the open winter, with its warm, damp weather, has not increased the death-rate; but, on the contrary, according to the tables prepared by the registrar of the Health Board, the deaths in this city during the twelve weeks between the last of November, 1879, and February 21, 1880, reached 3296, while for the same period last year they amounted to 4602, showing the deaths for this winter to have been 606 less than last year.

CARELESS USE OF ETHER.

A case illustrating the careless manner in which anesthetics may be administered occurred a few days ago. A lady took ether for some operation at a dentist's office, and shortly afterward started to go home. Being still under the stupefying effect of the ether, she stepped into a business college, and feeling very tired sat down, and was soon fast asleep. Waking up very much frightened, about two o'clock in the morning, she made an outcry and was soon liberated by the watchman, who had inadvertently locked her in. She was taken to the police station, and then restored to her anxious friends. Not long ago, a gentleman who had been taking nitrous oxide gas, in order to have some teeth attended to, started away before he had fully recovered from the anæsthetic, and fell down the steps, injuring himself considerably. In surgery the rule is never to leave the patient unattended for at least an hour after giving ether, but this does not appear to be the invariable practice among dentists.

Another honor has been conferred upon Professor Gross. The board of trustees of the Pennsylvania College of Dental Surgery has just elected him president of the board, in which capacity he presided at the recent Commencement of this, the second oldest dental college in the United States.

Two thousand five hundred and seventy-five deaths were reported; 990 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 421, consumption 414, lung diseases 404, diphtheria and croup 170, scarlet fever 70, typhoid fever 33, diarrheal diseases 32, measles 31, whooping-cough 30, cerebro-spinal meningitis 21, erysipelas 16, malarial fevers 11, typhus fever four, small-pox three. From *measles*, New York 13, Philadelphia six, Chicago five, New Haven three, Brooklyn two, Cleveland and Fall River one. From *whooping-cough*, New York 10, St. Louis and Cleveland three, Philadelphia, Boston, District of Columbia, Pittsburgh, and Charleston two, Brooklyn, Chicago, Cincinnati, and New Orleans one. From *cerebro-spinal meningitis*, New York four, Philadelphia and Chicago three, Cincinnati two, St. Louis, Baltimore, Buffalo, Cleveland, Lowell, Chelsea, Holyoke, Haverhill, and Newburyport one. From *erysipelas*, New York six, Philadelphia and Brooklyn two, Chicago, Baltimore, District of Columbia, Milwaukee, Charleston, and Worcester one. From *malarial fevers*, St. Louis four, Brooklyn three, New York two, Chicago and New Orleans one. From *typhus fever*, Philadelphia three, Buffalo one. From *small-pox*, Philadelphia two, Worcester one. One hundred and sixty-nine cases of measles, 31 of diphtheria, 29 of scarlet fever, two of typhoid fever, and one of whooping-cough were reported in Brooklyn; diphtheria 30, scarlet fever four, in Milwaukee; diphtheria 21, scarlet fever nine, in Boston; scarlet fever six, diphtheria three, in New Bedford. The death-rate of whites in District of Columbia was 19.61, of colored 41.8. Small-pox has entirely disappeared from Baltimore. In Norfolk, diphtheria was prevalent in February.

The total number of deaths reported was nearly the same as for the previous week, of deaths under five somewhat more. Lung diseases, diphtheria, and cerebro-spinal meningitis were more fatal, measles and small-pox less so. In 37 cities and towns of Massachusetts, with an estimated population of

1,025,560 (population of the State about 1,690,000), the death-rate was 22.47 against 21.26 and 20.22 of the previous two weeks, with a somewhat decreased rate of mortality from typhoid fever and whooping-cough.

For the week ending February 14th, in 146 German cities and towns, with an estimated population of 7,739,491, the death-rate was 27.5 against 26.9 and 25.7 of the previous two weeks. Four thousand and ninety-one deaths were reported; 1780 under five; acute diseases of the respiratory organs 622, pulmonary consumption 599, diphtheria and croup 143, typhoid fever 80, scarlet fever 70, whooping-cough 57, peripneumonia 32, measles and *röteln* 25, typhus fever one, small-pox (Bochum) one. The death-rates ranged from 15.0 in Wiesbaden to 45.8 in Frankfurt-on-the-Oder; Königsberg 26.9; Dantzig 30.9; Breslau 29.6; Munich 38.7; Dresden 22.2; Berlin 28.5; Leipzig 26.7; Hamburg 27.9; Hanover 19.4; Bremen 22.4; Cologne 29.7; Frankfurt 22.8; Metz 40.4. For the same week Vienna 28.8; Paris 37.8.—small-pox, diphtheria, typhoid fever, and lung diseases being very prevalent.

For the week ending February 21st, in the 20 English cities with an estimated population of 7,499,468, the death-rate was 26.0 against 31.0 and 37.0 of the previous two weeks. Three thousand seven hundred and forty deaths were reported. Lung diseases still further declined to 6.63, but exceeded the corrected weekly average by 213; whooping-cough 239, scarlet fever 120, measles 72, fever 51, diarrheal 44, diphtheria 18, small-pox (London) 13. The death-rates ranged from 12.2 in Brighton to 37.6 in Plymouth; London 28.7; Bristol 24.9; Birmingham 22.3; Liverpool 21.3; Manchester 26.3; Leeds 21.4. In Edinburgh 22, Glasgow 26, Dublin 38 (small-pox, six deaths). In the 20 chief Swiss towns scarlet fever, diphtheria, small-pox, and typhoid fever were the prevalent diseases; lung diseases continued to cause excessive mortality.

The meteorological record for the week in Boston was as follows:—

Date.	Barom- eter.	Thermom- eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MARCH 6, 1880, TO MARCH 12, 1880.

McELDERY, H., captain and assistant surgeon. Having reported in person at these headquarters, assigned to duty at camp at White River, Colorado. S. O. 19, Department of the Platte, March 5, 1880.

BROWN, P. R., captain and assistant surgeon. Assigned to duty at Fort Hamilton, New York harbor. S. O. 39, Department of the East, March 11, 1880.

MORSELEY, E. B., captain and assistant surgeon. Granted leave of absence for one month, to take effect when relieved by Assistant Surgeon McElerry. S. O. 19, C. S., Department of the Platte.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE WEEK ENDING MARCH 13, 1880.

PASSED ASSISTANT SURGEON H. E. AMES detached from the navy yard, Washington, and ordered to the U. S. S. *Saratoga*, vice Passed Assistant Surgeon A. F. Magruder, detached and ordered to the navy yard, Washington, D. C.

PASSED ASSISTANT SURGEON ROBERT WHITING ordered to the iron clads, Brandon, Va., vice Assistant Surgeon R. Ashbridge detached and placed on sick leave.

SIXTH DECENNIAL PHARMACOPEIA CONVENTION.

The following is a complete and corrected list of the delegates so far received by me:—

From the Massachusetts College of Pharmacy: Prof. G. F. H. Markoe, Ph. G., Samuel A. D. Sheppard, Ph. G., Thomas Doliber, Ph. G.

From the Philadelphia College of Pharmacy: Prof. John M. Maisch, Alfred B. Taylor, Prof. Joseph P. Remington.

From the Louisville College of Pharmacy: Prof. Emil Schaffer, Prof. C. Lewis Diehl, Vincent Davis.

From the Maryland College of Pharmacy, Baltimore, Md.: *Delegates*, William S. Thompson, Louis Dohme, Joseph Roberts, *Alternates*, Charles Caspari, Jr., Dr. J. F. Moore, Dr. Robert Lautenbach.

From the Medical Society of District of Columbia: Prof. David R. Hagner, M. D., Prof. Thomas Antisell, M. D., Emeritus Prof. James F. Morgan, M. D.

From the National Medical College of Columbia University, Washington, D. C.: Prof. W. W. Johnston, M. D., Prof. D. W. Prentiss, M. D.

From the Medical Department of Georgetown, D. C.: Prof. W. H. Ross, M. D., Prof. S. C. Busey, M. D., Prof. C. H. A. Kleinschmidt, M. D.

From the National College of Pharmacy, Washington, D. C.: Mr. W. S. Thompson, Prof. Oscar Oldberg, Mr. R. B. Ferguson.

Medical Department of University of Pennsylvania: Prof. Theodore G. Wornley, M. D., LL. D., Prof. Horatio C. Wood, M. D.

Massachusetts Medical Society: Dr. Robert Amory, of Brookline, Dr. Robert T. Edes, of Roxbury, Dr. Edward S. Wood, of Cambridge.

Bellevue Hospital Medical College: Dr. E. G. Janeway, Dr. A. A. Smith, Dr. F. A. Castle.

College of Pharmacy, New York: *Delegates*, Charles Rice, P. W. Bedford, Frederick Hoffmann. *Alternates*, H. J. Menninger, Paul Balluff, E. P. Nichols. Vacancies to be filled by president of college.

College of Physicians and Surgeons, Medical Department of Columbia College, N. Y.: Prof. Edward Curtis, M. D.

Dartmouth Medical College, Hanover, N. H.: Prof. H. M. Field, M. D.

Connecticut Medical Society: Prof. C. A. Lindsley, Yale Medical Department, A. Woodward, Franklin, Conn., C. W. Chamberlain, Hartford, Conn.

Rush Medical College of Chicago: Dr. W. S. Harris, Dr. J. S. Knox, Dr. J. H. Etheridge.

Philadelphia Medical Society: Henry H. Smith, M. D., Richard J. Douglass, M. D., J. Howard Taylor, M. D., State University of Iowa, Medical Department: P. J. Farnsworth, M. D.

Iowa State Medical Society: Dr. John North, Dr. P. J. Farnsworth.

JAMES E. MORGAN, M. D.,

No. 905 E Street, N. W.

WASHINGTON, D. C., February 26, 1880.

THE NATIONAL BOARD OF HEALTH has called a convention of all who are engaged in the work of registration of vital statistics for cities or States, and of others who are interested in the subject. The convention is to meet in Washington on the 6th of May next. The object of the meeting is to bring about a uniformity in the registration of vital statistics.

THE BOSTON DENTAL COLLEGE held its commencement on the 3d inst. at Parker Memorial Hall. After the exercises the class received their friends at Old Fellows' Hall, where the graduates made the president of the college, Dr. I. J. Wetherbee, a present of The Mock Trial, one of Rogers' groups. Twenty persons received their diplomas, and six more who passed the faculty will receive their diplomas when the period of their pupillage is complete.

E. P. George received the prize of a Johnston's dental engine, offered by Messrs. Hood and Reynolds for the best final examination, and A. F. Townsend, of the undergraduates, that of a case of Varney's packers, for best examination in anatomy and physiology and chemistry. Sixty-five students have been connected with the college the past year. A spring term for clinical work and study opens the 22d inst., under L. C. Bryan, D. D. S., demonstrator in charge. E. CHENERY, *Dean*.

APPOINTMENT.—Dr. George Steadman has been appointed associate medical examiner for Suffolk County.

BOOKS AND PAMPHLETS RECEIVED.—Ueber die Todesursachen nach Verbrennungen. Von Dr. L. von Lesser, Privat-Dozent für Chirurgie in Leipzig. (Reprint from Virchow's Archiv, 1880.)

Lectures.

A CLINICAL LECTURE ON SOME POINTS IN THE LIFE AND DIAGNOSIS OF CARCINOMA OF THE MAMMARY GLAND, BASED UPON A STUDY OF ONE HUNDRED CASES.

DELIVERED AT THE PHILADELPHIA HOSPITAL.

BY SAMUEL W. GROSS, M. D.,

Surgeon to the Hospital.

[From notes by Henry C. Boenning, M. D., Resident Physician.]

GENTLEMEN, — In the female wards there are four remarkable examples of carcinoma of the breast, which I shall bring before you this morning. After demonstrating their individual characteristics, I will devote the remainder of the hour, possibly exceeding the allotted time, to the consideration of certain points in the general pathology of carcinomatous tumors, and contrast them with the peculiarities met with in the non-carcinomatous neoplasms, with the view of establishing the differential diagnosis between these two great classes of new formations. The results at which I have arrived are based upon my private notes of one hundred cases of carcinoma, and upon one hundred and forty cases of the non-carcinomatous tumors, of which thirty-six are original. In order that we may understand one another thoroughly, let me premise that the term carcinoma, which I shall employ, interchangeably with cancer, to express a definite structure, is applied to an infiltrating atypical epithelial neoplasm, which is characterized, clinically, by local infection of the adjacent tissues and associated lymphatic glands, and by its marked tendency to general dissemination, and, structurally, by a cavernous fibrous stroma or framework, the meshes or alveoli of which are occupied by solid nests, plugs, or cylinders, composed of loosely heaped multiform epithelial cells, which are suspended in a serous fluid, without the intervention of a cementing intercellular substance. The non-carcinomatous tumors, on the other hand, embrace true adenoma, which is also derived from the lacteal glands, but which, unlike carcinoma, does not infiltrate the stroma, as well as fibroma, sarcoma, and myxoma, which are derived from the periglandular connective. Lipoma, chondroma, angioma, and neuroma are so rarely met with that, in speaking of the non-carcinomatous growths, I wish to be understood as referring only to adenoma, fibroma, sarcoma, and myxoma.

CASE I. Harriet L., aged forty-seven years, the mother of three children, the youngest of whom is fifteen years of age, states that she menstruated regularly up to one year ago, when the menopause occurred; that she is not aware of the occurrence of cancer among her ancestors or relatives; and that there has never been a discharge from, nor an eruption upon, the nipple. Five years ago she accidentally discovered a hard, painless lump, of the size of a small marble, beneath the nipple, which was movable under the skin. This lump increased so slowly that it required four years and a half, or until July, 1879, to attain the volume of an egg. In August it became the seat of sharp, cutting pains, which materially interfered with her sleep. About the first of September the tumor began to increase rapidly, and the entire breast was soon invaded by the disease. The pain grew worse; the nipple "got angry," and began to retract, and

several nodules made their appearance in the overlying skin. About the first of October, the integument was discolored; the entire gland was fixed to the pectoral muscle; a small, hard nodule was discovered in the right breast to the inside of the nipple, and the glands in both axillæ were found to be enlarged. During the past two months the progress of the disease has been rapid, and the suffering has been so great as to require large doses of opium.

To-day, — January 14, 1880, — you will observe that the disease is gradually spreading over the entire anterior surface of the chest. The left breast stands out prominently as a bossed, hard, hemispherical mass, as large as a child's head. The skin is tense, shining, and polished, everywhere attached, the seat of a purplish or bluish-red discoloration, and infiltrated by not less than fourteen flat, lenticular, or rounded nodules, which vary in size from a pea to a hazel-nut. In addition to these nodules the mamma itself is bossed, the largest projection, which is seated at its upper and inner periphery, being of the volume of a small orange, covered by a net-work of arborescent capillaries, and soft and elastic to the touch. Two weeks ago it gave way at a small point, and emitted about a tablespoonful of blood. The nipple is retracted to a level with the areola, and the sulcus is surrounded by a ruffle of elevations or tubercles. The skin between the breast and axilla is also occupied by small nodules, and the lymphatic glands of the axilla are converted into a densely hard, nodulated tumor, as large as a hen's egg, and closely adherent to the side of the chest. The glands below and above the clavicle are likewise converted into carcinomatous tissue.

Leaving the left side, the skin of the bosom, or the space between the two breasts, is seen to be occupied by numerous large tubers, some of which are discolored. The right mamma is only about one third as large as the left. It is still movable on the pectoral muscle, but it is firmly attached to the brawny skin, which is livid over the prominent bosses. The nipple is drawn in and surrounded, like its fellow, by a ruffle of nodules, and the subcutaneous veins are rather prominent. The glands of the right axilla form an adherent tumor almost as large, and equally as dense, as that in the left armpit. The supraclavicular glands and one below the clavicle are also involved.

As yet, despite her suffering, there are no very marked signs of interference with the functions of the organs essential to life. She is paler than she was a month ago, and her appetite is not very good. As nothing can be done in the way of permanent relief, we are making her as comfortable as possible by keeping her gently under the influence of morphia, and byunctions with stramonium ointment. In addition to these remedies she gets tonics and the best diet that the house affords.

CASE II. Eliza C., aged fifty-five years, the mother of two children, ceased to menstruate fourteen years ago, and is not aware of a family history of cancer. About two years ago, while washing the right breast, she accidentally noticed a firm, fixed, and painless growth, as large as an English walnut, two inches above and to the right of the nipple. She remained in this condition for twelve months, when the skin around the base of the mamma became ulcerated, and discharged a thin and fetid fluid. Excessive pain of a darting and cutting nature manifested itself at

the same time, and has continued ever since, with remissions in severity. She states that the original tumor gradually disappeared, and that small lumps, "like peas," made their appearance in the skin to the inner side of the affected breast, and extended to the opposite gland nine months ago.

The entire anterior surface of the thorax, this morning, looks as if it had been transformed into an irregular fungous mass, covered here and there with drops of blood and yellowish pus. On closer inspection, however, the red and prominent nodules and bosses are seen to be free from the ordinary appearances of fungus, their surface being, for the most part, merely excoriated or fissured, while some are covered by crusts. To the touch they are firm and somewhat elastic and tender. Varying in size from a small shot to an orange, they are multiform, convex on both surfaces, and inseparably connected with the chest. The discharge is profuse and has a sickening odor. Some of the nodules show distinct evidences of cicatrization of the superficial ulcers in the form of a thin epithelial covering, while one is sloughing off. The original breast and tumor are converted into a large, red, thin, adherent cicatrix. Of the left breast nothing remains except its lower half with the deformed nipple. Two small nodules of carcinoma are seated in the skin over the summit of the left shoulder, and are quite independent of the main mass. The supraclavicular glands of the right side are contaminated, and a cluster of hard glands, as large as an egg, is present in each axilla. The woman's general condition is excellent. With the exception of protecting the parts from friction with the clothing and overcoming tenderness and stench by an application composed of five grains of chloral hydrate to the ounce of petroleum ointment, which fulfills the indications capitally, nothing is being done.

CASE III. Elizabeth H., aged fifty-one years, the mother of six children, states that she ceased to menstruate at the age of forty-eight, and that her mother died of cancer of the breast. Two years ago she fell from a height of five feet, and struck her right mamma against the edge of a mowing machine. Three weeks subsequently she accidentally noticed a painless lump, as large as a hickory-nut, which was seated deeply in the gland, and the nipple was slightly drawn in. In about four months the nipple began to discharge a thin, reddish fluid, and one month later the breast became the seat of sharp, darting, stinging pains, which in the course of six weeks were so severe as frequently to keep her awake at night. At the end of ten months the glands of the axilla were observed to be enlarged, and the primary growth had attained the size of a hen's egg. Two months later, the breast having in the mean while almost doubled its volume, the glands above the right clavicle and along the posterior border of the sterno-cleido-mastoid muscle began to be affected, and a nodule appeared in the skin of the upper sternal region. At this time the breast and axillary enlargement were treated by painful caustic applications, through which the greater part of the tumors sloughed away. In fifteen months from its first appearance the disease had disseminated itself, in the form of small nodules, in the skin, over the greater part of the right chest, and appeared as a tuber in the left breast, near the nipple, and also infiltrated the glands of the corresponding axilla. Two months later spontaneous ul-

ceration ensued in the greatly enlarged sternal nodules, in the left breast, and in the left axilla.

Her general health has failed greatly within the last six months. Her appetite is very poor; she is frequently nauseated, and vomits after eating; and she experiences great pain in both breasts, in the right side of the neck, and in the right arm, which is somewhat swollen.

You will observe that the right mamma and a portion of the axilla are replaced by a huge, irregular, deep, funnel-like ulcer, with everted, indurated edges, showing, here and there, evidences of cicatrization, and a granulating surface, which bleeds easily on changing the dressings. The patient states that about two months ago the surface was covered with a blackish slough, which emitted a very offensive odor, but which ceased when the dead tissues were cast off, at the end of eight days. The mass over the sternum consists of two large, hard, and red tubers above, and of a superficial ulcer below as large as a silver dollar. The outer half of the left breast is converted into a densely hard tumor, which is ulcerated around and to the outside of the nipple, the latter of which is partially destroyed. The skin is infiltrated, below and to the outer side, by flattened plates of carcinomatous material. The glands of the left axilla are converted into a dense, round tumor, of the volume of a small apple, and the skin is superficially ulcerated, the edges of the sore being excessively hard and livid. The integument of the inner border of the left mamma, around the sternal growth, and over and below the right clavicle, is occupied by numerous shot-like and lenticular deposits, a few of which are as large as a filbert. The supraclavicular glands and the glands beneath and over the right sterno-mastoid muscle are converted into secondary tumors. The ulcers are being dressed with an ointment composed of five grains of chloral hydrate and a drachm each of extract of belladonna and extract of stramonium to the ounce of cosmolime; while internal medication is limited to the exhibition of opium to relieve pain, and the tincture of the chloride of iron with quinia to maintain her strength.

CASE IV. Mrs. McC., aged forty-five years, tells us that she is the mother of six children, the youngest of whom is five years of age; that she still menstruates; that there is no history of cancer in her family; and that, fourteen years ago, she accidentally noticed a lump, as large as a filbert, which moved only with the gland, and was seated at the lower portion of the axillary border of the right mamma. It developed so slowly that its growth was scarcely perceptible for three years, when it became painful and began to increase and involve the entire gland. For some years — just how many she cannot tell — it has been decreasing in size, and for the past six months has been the seat of constant, severe drawing pain, which is sometimes sharp and lancinating. Her general health is excellent.

A comparison of the two breasts shows great diminution of the affected one, it being probably not more than one sixth as large as its fellow. It is converted into a densely hard, puckered mass, in which the nipple is buried, and is immovably fixed to the pectoral muscle. There are no secondary nodules in the skin, as in the previous cases, nor is that structure discolored. The glands of the corresponding axilla constitute a stony, nodular tumor, of the volume of an egg, which is adherent to the side of the chest.

Although hard sarcomas and contracting fibromas have been confounded with carcinoma, the latter affection is marked by clinical characters which correspond so exactly with its minute structure that the diagnosis between it and other mammary neoplasms is readily determined by the experienced surgeon without a resort to the microscope. In the first three patients, the local dissemination of the disease, as determined, first, by the formation of secondary nodules in the skin and in the pectoral muscle, the latter being indicated by the deep adhesions or fixation of the original tumor; secondly, by extension to the opposite breast; and, thirdly, by the conversion of the associated lymphatic glands into carcinomatous tumors, is quite sufficient to stamp the true nature of the affection. In the fourth case, the deep adhesions and lymphatic involvement likewise point to scirrhus, although the primary tumor deviates from the ordinary type.

In order that you may understand to which of the varieties of cancer these cases belong, I must explain that they all come under the classification of fibrous or connective tissue carcinoma, which is equivalent to the clinical term scirrhus, and which embraces several divisions. Thus, in ordinary scirrhus the stroma preponderates over the collections of cells. In simple carcinoma the proportion between the cells and stroma is about equal, so that it stands midway between ordinary scirrhus and soft carcinoma. In the third form, which is known as atrophying, cicatricial, or withering scirrhus, the nests of cells are merely represented by fatty or granular detritus, or by rows of single cells contained in delicate, elongated, or fusiform clefts between the very abundant thick, tendinous, or sclerosed bands of fibrous tissue. The first three tumors I place in the class of simple carcinoma, which my experience teaches me differs from ordinary scirrhus in the following particulars: its cut surfaces do not become concave on section; its consistence is not so hard; its growth is more active, and its progress is more rapid, so that it attains a much larger bulk; and, finally, it is especially liable to regional dissemination, and to secondary involvement of the opposite breast. In regard to these three cases, I may say that they are remarkable in that the nodular infiltration of the skin seldom extends over the middle line of the thorax, and that both breasts are not often affected. In former days they would have been called lenticular cancer by Schuë, and pustular or disseminated scirrhus by Velpeau. In the second case, the changes which are met with in atrophying scirrhus are only needed to convert it into the cuirass form of cancer of Velpeau. The fourth case, which is one of withering scirrhus, is exceptional in occurring so early in life. It is said to be usually met with after the age of fifty-five, and to be the least malignant variety of cancer. While it is true that its course is more chronic, my experience with twelve cases is that it develops rather earlier in life, that it evinces signs of local infection and of glandular contamination incomparably more frequently than ordinary scirrhus, and that it is just as sure to terminate finally by general dissemination as the other forms. In one case of seventeen years' duration, which I have reported, there were secondary growths in the pleura, lungs, mediastinal glands, diaphragm, and kidney.

With the view of establishing a differential diagno-

sis between the carcinomatous and the non-carcinomatous neoplasms of the breast, which, after all, is what the surgeon most desires to do, I will now call your attention to the prominent points in their general pathology, as derived from the study of one hundred personal cases of the former, and one hundred and forty cases of the latter. And first as to certain conditions, or antecedents, in regard to the age of the patient and the functional activity of the reproductive organs, which are supposed to influence their development:—

CARCINOMATOUS TUMORS.

NON-CARCINOMATOUS TUMORS.

Age of Occurrence.

Appear, on an average, at the forty-eighth year. Three fourths develop after the age of forty, and never before the twentieth year. Hence, in impubertal girls the idea of carcinoma may be discarded.

Appear, on an average, at the thirty-third year. One third develop after the age of forty; one in six and one third before the twentieth year; and one in twenty before the establishment of menstruation.

Social Condition.

Ninety per cent. of the patients were married, and ten per cent. were single. Of the former, eighty-eight per cent. had borne children, and twelve per cent. were sterile.

Sixty-one per cent. were married, and thirty-eight per cent. were single. Of the former, eighty-six per cent. had borne children, and fourteen per cent. were barren.

Menstrual Function.

Sixty-five per cent. were menstruating when the growth was first observed.

Ninety-three per cent. were menstruating when the tumor was first noticed.

The generally received opinions in regard to breast tumors are that the development of the simple ones is favored by celibacy, sterility, disordered menstruation, and a nervous or hysterical disposition, while the carcinomatous growths are influenced by pregnancy and the menopause. Without going fully into the subject, I will merely say that these statements appear to me to be unfounded. A comparison of the table will show that an almost equal number of women in each class had borne children, and that the apparent differences in the menstrual function and the social state may be explained by the fact that fewer women, the subject of the non-carcinomatous neoplasms, are to be expected to be married in consequence of their comparatively early age, while more, for the same reason, are menstruating. I may further say that in this class ninety-three per cent. were regular as to the catamenial function, and only three per cent. were hysterical. Hence I conclude that these points are scarcely worthy of consideration in the differentiation of tumors of the mamma. In regard to age, I will add that the simple neoplasms develop earlier in life, because the unknown causes which excite tumor formation act upon an organ which preserves its structure and nutrition unimpaired, while later in life, when the mamma is losing or has lost its structural perfection, carcinoma shows itself, because the obsolescent lacteal glands proliferate in an atypical way. Hence, in the development of new growths, the condition of the component elements of the mamma at different periods of life is to be considered rather than any influence that may be exerted upon it by the state of the genitalia.

Hereditary predisposition, injury, and previous disease are also supposed to favor the development of the carcinomatous neoplasms; and this looks plausible, if we exclude trauma, which preceded the formation of both classes of tumors in an equal proportion, that is, in one case out of every nine. Thus heredity was traceable in one case out of every twelve and a half

of the carcinomatous, and in none of the simple growths. Mastitis, or a lump left after parturition, appeared to be the exciting cause of cancer in one case out of every twenty, while it did not precede the appearance of the other tumors. Eczema or psoriasis of the nipple or areola antedated carcinoma in one case out of every fifty, while it was met with only in two cases out of one hundred and forty of the non-carcinomatous neoplasms, and these were examples of adenoma and cystic sarcoma.

Leaving the presumed causes, of which really we are in the dark, let us now examine the clinical features, which alone are valuable in framing a diagnosis:—

Situation.

Most common at upper and outer margin, and not infrequent near the nipple.

Usually at the upper and inner circumference. Rarely near the nipple.

Outline.

Irregular, slightly tuberos, knotted or knobby, frequently discoid, and merged into the surrounding tissues.

Round, ovoid, rarely discoid, lobed, bossed, or nodular, and distinctly circumscribed.

Consistence.

Uniformly densely hard and inelastic throughout, except in rare instances of combination with an involution cyst, when there is a limited spot of fluctuation. As an exception, may be firm and elastic, or even soft and fluctuating.

All are firm or hard at first, and frequently elastic; but not a few are soft later. Many are of unequal consistence, when they have existed for some time, in which event they are hard at some points, and soft, or even fluctuating, at others.

Multiplicity.

Several tumors are present in the same breast in one case out of every fifty.

Several tumors present in the same breast in one case out of every sixteen and one half.

Volume and Rate of Growth.

Never reach the dimensions of the simple tumors, and usually smaller than the breast which they have substituted. Grow continuously and comparatively slowly, and are quite liable to shriveling of the stroma, particularly when they occur late in life.

May attain a huge size. Frequently increase by fits and starts; grow comparatively rapidly; and do not, except in rare cases of fibroma, undergo cicatricial atrophy.

Mobility.

Move with the gland of which they form a part, and cannot be isolated. Attachments to the skin and chest are common and frequently extensive.

Slide and roll under the fingers, and move freely within the mamma and on the adjacent parts; or if there be attachments, which are exceptional, they are limited.

Relations to Breast.

If the tumor develops within the substance of the mamma, the latter is substituted by it, and its structure is destroyed. When it begins at the periphery, the gland is always finally invaded.

Now and then attached to the breast by a pedicle; but the gland is usually pushed to one side, spread out, or atrophied, and rarely completely invaded.

State of the Nipple.

The nipple is permanently retracted and fixed in one case out of every two (fifty-five cases), and is often infiltrated.

The mamilla, in one case out of every twenty (seven cases), is displaced, buried, or sunken, by the growth of the tumor beyond its level. Hence it is mobile and not truly retracted, and is free from infiltration.

Discharge from Nipple.

A thin, sanguinolent discharge is met with in one case out of every eleven and one ninth (nine cases); but it is never copious.

A discharge, usually of a mucoid nature, is met with in one case out of every eleven and three fourths (twelve cases); and the escape of bloody fluid favors the idea of vascular vegetations in dilated ducts.

Superficial Veins.

The veins are prominent in one case out of every fifty (two cases).

The superficial veins are enlarged and tortuous in one case in every eight and three fourths (sixteen cases).

Condition of the Skin.

The skin, even when the tumor is not larger than a hazelnut, provided it be superficial, is dimpled and adherent. In large tumors it is adherent, thinned, or discolored, or rigid and brawny from specific infiltration, in one case out of every five (twenty-one cases), and the seat of secondary nodules in one case out of every six and two thirds (fifteen cases).

The skin is smooth and natural when the tumor is of moderate dimensions, but thinned and stretched or discolored in one case out of every five and three fifths (twenty-five cases), or adherent to a limited extent in one case out of every eight and one fourth (seventeen cases), when the tumor is voluminous. It is never dimpled, nor the seat of secondary growths.

Deep Adhesions.

The tumor is fixed to the pectoral muscle or thorax in one case out of every seven (fourteen cases).

The tumor is adherent to the subjacent tissues in one case out of every seventeen and one half (eight cases).

Both Breasts Affected.

The other breast is invaded in one case out of every thirty-three (three cases), but never before infection of the skin and lymphatic glands.

The opposite mamma contains a similar growth in one case out of every twenty (seven cases), but without antecedent skin or glandular involvement.

Ulceration.

Ulceration ensues, comparatively early, in one case out of every five and one fourth (nineteen cases). The edges of the sore are everted, thick, and indurated, and adherent to the hardened base. It never attains the size met with in the simple tumor, does not fungate, nor does it cicatrize to any great extent.

Ulceration, or limited gangrene, of the stretched and thinned integuments occurs, late in the disease, in one case out of every five and three fifths (twenty-five cases). It is generally attended with the protrusion of a pedunculated fungus, which is not attached to the sides of the ulcer, the edges of which are smooth, even, and not discolored or infiltrated. The base is usually composed of vegetations, and it now and then heals.

Lymphatic Glands.

The axillary lymphatic glands are enlarged and hard, when the patient first comes under observation, in rather more than one case out of every two (fifty-five cases), and in one fifth of these the glands of the neck are also involved.

Enlargement of the axillary glands is met with in one case out of every twenty-eight (five cases), but it is due almost solely to irritative changes, and they are not hard. The supraclavicular glands are never enlarged.

The points in favor of carcinoma are, therefore, non-development before the age of twenty, greatest frequency after the fortieth year, irregular shape, almost uniformly densely hard and knobby feel, immobility in the gland, attachments to the skin and deeper structures, solitary origin, comparatively small volume and slow growth, retraction of the nipple, infiltration of the lymphatic glands, invasion of the skin by small nodules, non-enlargement of the subcutaneous veins, limited ulceration, without any tendency to fungous protrusion, and the thickened, indurated, and everted edges of the ulcer.

The diagnosis of the non-carcinomatous tumors is based, on the other hand, upon their occurrence in every sixth case before the age of twenty, their greatest frequency before the fortieth year, their multiplicity in one breast, their peripheral situation, their rounded or ovoid and bossed outline, the firm consistence of the smaller and the unequal feel of the larger, their mobility in or on the gland and the adjacent tissues, their comparatively rapid growth and bulky size, the natural appearance of the skin, the enlargement of the subcutaneous veins when they are voluminous, their tendency to ulcerate and protrude late in the disease, and the absence of adhesions between the fungus and margin of the ulcer, and their freedom from retraction of the nipple, nodules in the skin, and taint of the associated lymphatic glands.

There are many interesting and highly instructive features in the symptoms of both classes of tumors

which I might, had I the time, discuss with profit; but as I have considerably overrun my hour, I will limit my remarks to two points.

Among the more prominent signs of carcinoma are those which indicate local infection of the surrounding tissues, and a knowledge of the date of their appearance will prove serviceable in deciding the question of an operation. Nodules may be looked for in the skin in fourteen months, the contaminated lymphatic glands of the axilla may be detected in fifteen months, ulceration may be expected in seventeen months, and deep adhesions take place in twenty-one months. These figures denote the average date; but I have known infiltration of the skin, pectoral muscle, and glands, and ulceration, to occur as early as four months, and to be postponed, on the other hand, for several years. Glandular involvement, indeed, may show itself as early as the first month, or even before the primary tumor can be felt; and from the fact that the glands are buried in the fat of the axilla, thereby evading early detection, I believe that their invasion antedates that of the skin. Be this as it may, if you are about to operate on a case in which there is nodular infiltration of the skin, you should be prepared to open the axilla and search for infected glands, even if they cannot be distinguished from without.

Finally, I desire to state that I am no believer in the constitutional origin of carcinoma, and that I am convinced that we will obtain good results after operation if we can only secure cases in which the disease is limited to the gland itself. Even when the skin over the breast is infiltrated to a slight degree, and the lymphatic glands of the axilla are not too seriously involved, I believe that we may prolong life, if not obtain a radical cure, by extirpation. To do this, however, you must discard the operation as you usually see it performed, and remove the entire gland, with all its coverings, by a circular incision, dissect away the pectoral fascia, and clean out the axilla. In other words, do not aim to secure a covering for the wound, but practice thorough excision.

Original Articles.

HINTS UPON THE TREATMENT OF PARALYSIS IN EARLY LIFE.

BY HENRY G. DAVIS, M. D.

I WILL not attempt to discuss the various causes of this particular affection, or to rehearse in detail its symptoms, mode of attack, parts most liable to suffer, or its special pathology. Such a course would be foreign to my purpose, as my intention is merely to give some hints in regard to the treatment of that class of paralytic troubles that are in the majority of cases purely functional when they present themselves for treatment. In using the term "functional paralysis" that condition only is meant where the paralysis remains after the cause is apparently removed.

Before proceeding farther, allow me to draw attention to a marked difference in the tendency to recovery unaided by treatment between adults and infants when similarly attacked with paralysis of one or more limbs. This difference is not recognized, yet it is so marked in our experience that it very materially controls our special course of treatment.

An adult paralyzed, when the cause is removed, begins to use his muscles in accordance with his former habit, and his recovery may be rapid. On the other hand, if an infant becomes afflicted in a similar manner, it is very seldom that it recovers the use of all the muscles affected. The reason why there is this difference appears to be this: The adult *before* his attack has a perfect use of his muscles; he has formed the habit of moving certain muscles for the accomplishment of certain purposes; this is so much a habit that he is not conscious of exercising any act of volition. This habit has been so confirmed by constant exercise previously that when he is ready to make a trial of his muscles they are brought into action in the same order and in the same manner in which they had been trained before his paralysis. The force of habit controls his efforts, and he attempts to move his limbs as formerly. In the child, however, a very different state exists; in his efforts he is neither guided by his reason nor by the force of habit. He is not capable of making any systematic movements of the paralyzed muscles from habit or reason.

In the paralysis of infants, the attack is at so early an age that they have not formed any habit in locomotion. Hence, when the cause is removed, they are like infants, but without any nervous influence, as it were, compelling them to move their limbs. In these cases the patient should be put under a regular system of education, training him to direct through the will the nervous influence to particular muscles. The patient has lost the way or the process by which he can by an act of the will move any of the affected muscles.

It is for the purpose of calling the attention of the profession to this particular point that I am induced to offer a few remarks.

The mode of treatment which I have been led to adopt is very simple, and my experience in the treatment of a number of cases has taught me to place confidence in its efficiency.

The first effort should be to associate the mind of the patient with some particular action of the paralyzed limb, and concentrate the will upon the movement of some particular muscle. These movements must be made first by the surgeon's assistance, the mind of the patient being for the time kept constantly directed to the parts. This can be more readily accomplished if the corresponding motions of a sound limb can be made at the same time, associating the movements of the muscles of the paralyzed limb with those of the well one. Let us take, as an example, a child that has been paralyzed for some time in one of the lower limbs; there is absolutely no power whatever on the part of the little one to move the affected member. The child is placed in front of the operator, the well limb is exposed to the knee, and the little one is shown how the patella can be made to move by his making certain efforts. When he has been so trained that he can always contract the muscles of the well limb that are inserted into the patella, and has received the idea that it is done by an act of his own will, then the paralyzed limb can be placed by its side, and his attention directed to a similar and simultaneous effort to draw up the patella, while at the time of his effort the surgeon raises the limb in unison with the other. This should be repeated until the muscles of both limbs will contract simultaneously and by the action of the will of the patient.

This voluntary action of a muscle paralyzed encourages and aids its growth much more rapidly than any mode of simple passive exercise. It is effected by the same law that increases the size and power of a muscle that is in a normal condition, namely, a natural exercise or use of it. As I have before intimated, if both the lower limbs are similarly affected, the difficulties in the way of a speedy cure are somewhat greater, requiring more time and patience, but the principle of treatment remains the same.

The length of time required to effect a cure varies, of course, with the circumstances attending each particular case, as the age of the patient, the length of time since the attack, the aptitude of the child to follow instructions, the success of the surgeon in controlling his attention. The time required to restore a useful limb will also depend upon the amount of atrophy of the muscles. It matters not to what extent muscles have wasted, as this does not prevent a recovery. If it can be perceived that the muscles are influenced in the least by the will of the patient in his efforts, a restoration is quite certain. A medical friend in New York stated to me a case of paralysis of the deltoid muscle occurring in early childhood, which serves to illustrate this, in rather a remarkable degree, and it has been corroborated in my own practice. The patient had suffered, as has been said, from early childhood. During this time the loss of motion was constant. There was not the slightest trace of muscular substance; there was nothing but the integuments covering the locality where the muscle should have been. By treatment the muscle was fully restored.

So confident am I of the success of this particular method of treatment of functional paralysis by the education of the will that I think it can be fairly assumed that if it fail, after a persistent, patient, and systematic trial, there must be some organic lesion, either of the nerves supplying the muscle of the part, or of one of the nervous centres.

This was the condition of a boy, nine years of age, who came under my care for paralysis of the right lower limb that had existed since infancy. In this case not the slightest connection could be found between the brain and the paralyzed limb, not even by electricity or strychnia. This case is the only one in which I have failed of producing a favorable result. Electricity causes contraction of the muscles, without the influence of the will. If the will is not educated to send nervous influence from the brain, the patient remains the same so far as a voluntary use of the muscles is concerned. Friction causes a flow of blood to the part, and thus increases nutrition, but it is in a great measure of the cellular substance, and not of the muscular fibre.

Unless the connection between the will and brain of the patient is established, and the muscles respond to the will, what possible ultimate benefit can be expected when the electric current is stopped or passive rubbing ceases?

As soon as these unnatural stimulants cease there is a tendency to retrogression, unless *during the process* the lost connection of the brain or will with the muscles is restored. By enabling the patient to send the nervous influence to a muscle, and thus exercise it, the fibre of the muscle is increased much more rapidly than the cellular tissue.

In order to illustrate this point more fully, I may be permitted to refer to a case, at the same time

taking advantage of the opportunity to go somewhat minutely into the method of treatment employed in the case: A boy, four years of age, was placed under my care, who was paralyzed in the right lower limb when eighteen months old, at a time of life when the correct habit of walking had not been fully formed. He had no use of the muscles of this limb, except a slight power over the toes, which is not an unusual feature in these cases. As far as an ability to make any coordinated motions, such as are to be noticed in the complex effort of walking, there was none whatever. The muscles and nerves were there, yet from the entire neglect and disuse of them for the long period mentioned the brain had practically ceased to regard them as a part of the system. I seated him in a chair, and went through with a systematic course of training in the manner before detailed.

The flexors and extensors were first operated upon, and the movements were made in common with similar movements of the sound limb, the attention of the patient being directed at the same time towards making an effort to aid the action of the paralyzed muscles. After considerable trouble I succeeded in effecting a movement of the rectus femoris, so that it plainly twitched under the eye. Subsequently I arrived at a stage in the treatment which warranted me in allowing him to stand and bear the weight of his body, cautiously, upon the unsound limb. While in this position he soon became able to flex and extend the limb, and take his first lesson in self-progression. He finally became able, by dint of a considerable amount of voluntary effort, to take a few steps. This he could do tolerably well (with the aid of a crutch, of course) as long as his whole, undivided attention was directed to the proper performance of the act; but if his mind were drawn off, even temporarily, from its purpose, although he might continue the attempt at locomotion, the paralyzed limb would remain motionless. This was a uniform result, and by watching his countenance it could be known when he would fail to move his limb. This result is mentioned to show that although he had acquired the power he had not the habit.

This shows in a marked degree how essential is the influence of the mind in restoring motion to paralyzed muscles. The sequel of this case was very satisfactory, and serves to illustrate the necessity of long-continued and persistent education in order to confirm the habit, until it becomes, as it were, involuntary. When such a habit of walking is formed in the child he can safely be said to be cured.

As an encouragement to the effort of educating the will to control properly the muscles in these cases, I may state that a child, after paralysis, if left to himself, will generally, nay, almost unavoidably, acquire an awkward habit of walking, which he will probably retain through life.

If a child recovering so as to be able to stand upon one limb, with his hands upon a chair, is noticed, when he wishes to move he pushes the chair, and then hops upon the well limb, dragging the other. If anything catches the sole of his shoe in this effort, so that he cannot drag his limb, if he is ingenious he will lift the limb by the pelvis, so as to overcome the obstacle. Then, as soon as he has found out how to bring the knee back of the centre, as in using an artificial limb, he will begin to use it for walking; and this style of locomotion he may retain through life, when, if he had been properly trained, he might have recovered the

ordinary grace of movement. In these cases there is not absence of all connection between the brain and the paralyzed muscles, but a want of knowledge of how to affect them, or how to communicate with the muscles. The great difficulty, after all, is to find or continue some movement or process by which the patient shall bring his will to act upon the paralyzed muscles. The function of the brain is restored apparently in these cases, but knows not how to use its power.

In certain cases of paralysis a deformity follows by the contraction of some muscles. In these cases the paralysis is overcome when the limb is restored to its normal position. A boy came to me from Connecticut in this condition, who recovered the use of his muscles as soon as the deformity was remedied. A young lady came to me from Iowa, aged sixteen, with dislocation of the femur upon the dorsum of the ilium, turning her foot so that she walked upon the side where it was fixed. She had lost all use of those muscles that were necessarily unemployed. After the hip was reduced and the foot brought into place, she recovered entirely the use of the muscles of the foot and a perfect control of the limb. I could add any number of illustrations from patients treated, but let these suffice.

I will state two cases to show that a long existence of the paralysis does not always interfere with a rapid recovery:—

A young lady from Troy, New York, came under my care, with paralysis of both lower limbs since early life. They were strapped with irons both inside and outside of each limb, extending from the pelvis to the sole of her boots, with a contrivance at the knee for rendering them inflexible. She walked with crutches, swinging both limbs forward, and the irons being stiff she could bear her weight upon them as upon two artificial limbs. When the irons were taken off the ankles would come to the floor, so lax were the ligaments. I removed all apparatus, and commenced training her to use the muscles. Being an intelligent girl and anxious to get well, she made every effort to accomplish what I desired. In three weeks, while resting upon her crutches, she could take up either limb and move it forward, as in the act of walking, and eventually recovered so as to walk without any artificial support.
